The Goulstonian Lectures

ON

SOME ABNORMAL PSYCHICAL CONDITIONS IN CHILDREN.

Delivered before the Royal College of Physicians of London on March 4th, 6th, and 11th, 1902,

BY GEORGE F. STILL, M.A., M.D. CANTAB., F.R.C.P. LOND.,

ASSISTANT PHYSICIAN FOR DISEASES OF CHILDREN, KING'S COLLEGE HOSPITAL; ASSISTANT PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

LECTURE II.[1]

Delivered on March 6th

MR. PRESIDENT AND GENTLEMEN,—In my first lecture I drew your attention to some points in the psychology and development of moral control in the normal child and then considered the occurrence of defective moral control in association with general impairment of intellect; before going further it may be well to review briefly the points which have been raised. Moral control, we saw, is dependent upon three psychical factors, a cognitive relation to environment, moral consciousness, and volition, which in this connexion might be regarded as inhibitory volition. Moral control, therefore, is not present at birth, but under normal psychical conditions is gradually developed as the child grows older. The variation in the degree of moral control which is shown by different children at the same age and under apparently similar conditions of training and environment suggested that the innate capacity for the development of such control might also vary in different individuals.

Proceeding, then, with our inquiry as to the occurrence of defective moral control as a morbid condition in children we considered the occurrence of this defect in association with idiocy or imbecility and saw that whilst defect of moral control is often associated with general impairment of intellect there is no constant proportion between them; the child with only slight intellectual impairment may show far greater moral defect than a child with more impaired intellect. There appeared to be no grounds for connecting any particular type of imbecility specially with moral defect, and beyond the fact that such physical changes in the brain as produce general impairment of intellect may also produce defect of moral control, it was impossible on the clinical evidence available to attribute the moral condition exclusively to any particular structural abnormality Whatever the cause of the defect may be, it seems clear that in these cases there is a morbid limitation of the capacity for the development of moral control, and the fact that this limitation is not necessarily proportionate to the limitation of capacity for general intellectual development seems to make it at least conceivable that the mental processes involved in moral control may be affected altogether apart from those concerned with more general intellectual acquirements. I propose now to bring forward evidence that this isolated affection of moral control does actually occur.

MORBID DEFECT OF MORAL CONTROL ASSOCIATED WITH PHYSICAL DISEASE.

In considering defect of moral control apart from general impairment of intellect it must, I think, be recognised that the morbid character of such a defect may be shown not only by its degree as compared with our empirical and arbitrary standard for the age and by its non-correspondence with the influences of environment, but also by the fact that the failure of moral control is entirely at variance with the previous habit, if I may so say, of the particular child; and this is a point of some practical interest, for, as we shall see, in some cases comparatively trivial manifestations which, if they were habitual in the child, would be regarded as quite within the limits of normal variation, assume a considerable importance as premonitory symptoms of physical disease.

Perhaps the most conclusive evidence of the morbid character of deficiency of moral control in some cases where it is not associated with general impairment of intellect is to be found in its close relation to physical disease, which I shall now consider. Naturally one turns first to cases with gross lesions of the brain, for here, if anywhere, we should expect that physical disease might cause alteration of moral control. Unfortunately for the purposes of my argument, where the lesion causes any psychical change, it is so apt to produce also some general disorder of intellect that many such cases—for instance, cases of infantile hemiplegia—fall rather into the group which I have already mentioned than into that now under consideration. There are, however, a sufficient number in which the moral alteration is unaccompanied by any general disturbance of intellect, to establish the fact which I wish to insist upon.

Cerebral tumour.—A girl, aged 10 years and nine months, was under my care about six months with symptoms of pontine tumour, paralysis of the sixth and seventh nerves on the left side, and paresis of the right arm and leg, only occasional headache, and then not severe, no vomiting, no fits, and no optic neuritis up to a few weeks before death. The child's general intellectual power seemed unimpaired up to the last time I saw her, about a fortnight before she died; but about two or three months after she first began to ail (the whole duration of the disease was about nine months) a change was noticed in the child; she had previously been good-tempered and obedient, she now became extremely passionate, if the food at meals was not exactly to her liking she would fling it across the table and the slightest thwarting of her wishes by her seven-year-old sister produced an outburst of rage in which she would attempt to strike her sister on the head, she was extremely self-willed and the mother repeatedly complained of the difficulty of managing her. This child was at the same time extremely emotional, a point to which I shall refer again. The necropsy showed a new growth infiltrating the pons, but more on the left side than on the right; there was some flattening of the cerebral convolutions and the whole cortex was unduly hyperæmic. The ventricles were little if at all dilated; there was no trace of new growth above the level of the pons.

Very similar was the case of a boy, aged seven and a half years, who had symptoms of intracranial growth, occasional occipital headache, fits involving chiefly the right side, vomiting and optic neuritis, with some weakness of the left external rectus and exaggeration of the knee-jerks 12 months after the first onset of symptoms the mother noticed a change in the boy's behaviour, without any general disturbance of intellect, he became extremely passionate, the least irritation—for example, his brother accidentally and very gently pushing against him—threw him into a passion in which he clenched his fists and screamed; these outbursts occurred many times a day, sometimes he would attack his brother in his passion; he had also become very disobedient, whereas previously he had been a good-tempered and obedient child.

Infantile hemiplegia may, as in a case I mentioned in my previous lecture, cause moral deficiency in association with general intellectual impairment, but in the following case it affected only the moral condition. A boy, aged about four and a half years, had left hemiplegia dating from the age of 20 months; he was an attractive child, very intelligent, and talked brightly, he was, however, extraordinarily spiteful, for instance, if knives or forks were available he would suddenly throw them at people when they were not looking, and the mother was afraid that he might do some serious injury; whilst walking in the street he had attacked with a stick children who were quite strangers to him; he had been sent to school, but was quickly sent home again as too spiteful to be allowed with other children; he was extremely passionate and if crossed in any way threw himself on the floor and screamed. Corporal punishment had been tried at times but the mother said that it made not the least difference in the boy's behaviour

Meningitis, as is well known, is sometimes ushered in by symptoms like mania but without any such profound intellectual disturbance; loss of moral control may be an early, if not the earliest, symptom. For instance, a girl, aged about 10 years, was reported by her school teacher to have unaccountably changed from an obedient well-behaved child into an extraordinarily disobedient and unruly one About a week later she became drowsy with headache and other symptoms, which pointed unmistakably to tuberculous meningitis, from which she died. In another case a boy, aged four years, after recovery from posterior basic meningitis became ludicrously passionate, beating himself in fury if meals were not ready directly he wanted them.

---

[1] Lecture I. was published in THE LANCET of April 12th, 1902, p 1008.

Epilepsy also has a close relation to moral deficiency. As I have already pointed out, the imbecile with epilepsy is apt to be distinguished by his lack of moral control; as I shall show later, convulsions or epileptic attacks not infrequently figure in the early history of children who in later childhood come under observation for defect of moral control. Moreover, quite apart from any general impairment of intellect, the approach of an epileptic seizure is preceded in some children by a definite moral change. A girl, aged 10 years, who had had frequent fits since the age of 14 months, was always troublesome to manage, self-willed, disobedient, and passionate; on one occasion at the age of six years on receiving some new clothes which did not please her she flew into a passion and tore them up. These characteristics were noticeably increased for one or two days before the onset of an epileptic attack, the child at such times becoming extremely disobedient and difficult to manage. Another child, a boy, although much younger (just over three years old), may serve to illustrate the same change. He had had fits for the previous four months; their onset was said to be preceded by extraordinary excitability and spitefulness, which began two or three days before the fit, and at such times he had bitten people, and, indeed, bit a baby, aged 11 months, sufficiently severely to draw blood. Neither of these children who suffered from epilepsy showed any general disturbance of intellect.

Head injury in a boy, aged six and a half years, appeared to be the cause of a temporary loss of moral control. The boy fell down some steps, striking the left side of his head and producing a large hæmatoma which covered the whole of the parietal bone. Within a few days after the fall it was noticed that the boy's behaviour was "different altogether," so the mother said, from what it had been previously. He had now become spiteful, passionate, disobedient, and destructive. When given bread-and-milk which he did not want he flew into a passion and knocked it off the table; when told to do something against his wishes he struck his mother in the face; he had also struck the baby only nine months old; and when a little boy and girl of whom he is usually very fond came into the room he threatened that if they did not go away he would throw his toys at them, which he forthwith did; when told that his little brother, of whom he is particularly fond, was going away from home he said he was glad to get rid of him; he also tore up books and threw them in the fire. He showed no general disturbance of intellect, unless one remark made on the fourth day after the injury can be taken as evidence of a delusion. He said that his toast at breakfast was "poisoned" and he would not eat it; but there was no other evidence of any delusion, and it seems doubtful whether this remark was not rather an exaggerated expression of dislike than an actual delusion.

But it is not only with physical disease or injury directly affecting the brain, but also in relation to physical disease of more general nature, that loss of moral control is seen.

Typhoid fever in children, as in adults, is sometimes followed by a temporary insanity, but without any such general disorder of intellect the moral character may undergo a definite alteration. A girl, aged 10 years, was in the Children's Hospital suffering from typhoid fever which was severe and complicated by otitis media. For several months after this the child, who had previously been a well-behaved child, was extremely disobedient and unruly; she was spiteful and passionate. Her general intellectual condition appeared to be normal. The moral alteration persisted for some months, after which the girl gradually regained her former condition.

Diphtheria was followed by a similar change in a boy, aged five years and two months, who after the acute illness seemed nervous and excitable. He became extremely passionate; he threw a knife at someone who had crossed his wishes and on the slightest provocation he would scratch, kick, or bite; he also became disobedient and mischievous and a few days before I saw him he deliberately set fire to some clothes, apparently in a spirit of defiance, having just been warned of the danger. The boy showed not the least general impairment of intellect but there was a history of epilepsy in his sister and probably also in his uncle and aunts.

Scarlet fever in a case recorded by Dr. Hack Tuke[2] had a similar sequel. "A gentleman's son, a boy of five years old, favourably circumstanced in his moral surroundings, had an attack of scarlet fever. He recovered, but his moral character had undergone a remarkable change. Instead of being a truthful, he became a very untruthful, lad. For a time he was honest, then he began to take what was not his own without the slightest occasion for doing so. A further stage was reached—he evinced a disposition to injure others." Subsequently as a young man he had to be placed under special supervision to prevent some criminal act. In another case,[3] recorded in America, a girl was normal in every way until seven years old, when she had scarlet fever, with convulsions and delirium. On recovering from the fever she appeared to have lost her moral control. She could no longer be made to obey, she displayed violent paroxysms of passion, she had become untruthful, and when eight or nine years old she showed a marked tendency to sexual immorality. It was specially noted that there was "no intellectual impairment; she was, on the contrary, exceptionally bright." "She keenly distinguished right from wrong and only seemed lacking in the power or will to control herself." It was noteworthy that the father of this child had been melancholic and had committed suicide.

Acute rheumatism seemed to be directly related to moral alteration in a boy, aged nine years, who after an attack of rheumatic fever at seven years of age was ailing with pain in the præcordium and frequent palpitation of the heart; there was no bruit and no obvious dilatation of the heart. These symptoms lasted for some months after the acute onset and about six months after the rheumatic fever the boy, who had previously been a good-tempered, tractable child, became violently passionate; in his rage he would attack anyone with extreme fury. These attacks occurred once or twice a week, generally after some slight provocation. He was spiteful and recently had shown a disposition to kill himself. The boy had a furtive look, and whilst in the hospital he was found one morning with a draw-sheet twisted round his neck, but otherwise he showed nothing abnormal. All these symptoms gradually diminished, but at about 12 and a half years of age he had rheumatic fever again and after this again became more spiteful, taking pleasure apparently in wantonly inflicting pain on his brothers and sisters and laughing immoderately when he had succeeded in hurting them; he was also at this time extremely passionate, clenching his hands and turning pale with rage, and then pouring forth abuse. He got on well at school and seemed to be perfectly normal in intellect apart from his lack of moral control. He had convulsions during his second year and his mother had epileptic attacks for two years, from 16 to 18 years of age. Dr. Savage has referred to a similar occurrence,[4] a severe attack of rheumatic fever being followed by moral perversion.

In all these cases it seemed clear that there was a close relation between the psychical and the physical conditions, that both in fact were morbid manifestations, and in none of the cases was there evidence of any general disturbance of intellect. So that here we have, I take it, instances of a morbid alteration of moral control without any general impairment of intellect. In almost all these cases the moral change consisted in a loss of already acquired moral control; but had the physical disease occurred at an earlier age, before the development of moral control, it seems only reasonable to suppose that the moral development would have been arrested or delayed; and, indeed, this appeared to have happened in the case of infantile hemiplegia to which I have referred. This point is of some importance in its bearing on the etiology of the group of cases which I shall consider later.

The loss of so complex a mental function as moral control in children with physical disease is no doubt in part referable to its recent development, and therefore "unstable equilibrium," if one may so say; and one might compare with this the loss of speech which sometimes occurs in very young children as the result of any illness whilst speech is still in process of acquirement, and we must remember that moral control is later and much more gradual in its development than speech. This, however, is only a comparison, and whilst it seems probable that some of these cases do indicate such a retrograde change to the conditions of an earlier age, in others there would seem rather to be a morbid perversion of one or other of the mental processes concerned in moral control; in some of them there is evidently an insufficiency of inhibitory volition, as may be seen from the general excitability and emotionalism which accompanies the moral failure; in others there would seem to be a perversion of moral consciousness, which one might compare with the perversion of appetite, the craving for disgusting substances, such as earth, tallow, &c., which one sometimes sees in children who are out of health and who lose their unnatural craving when their general health improves. Whatever may be the psychical alteration in these cases they at any rate emphasise the point upon which I have already insisted—namely, the differentiation of moral control from other mental functions, albeit dependent upon the same fundamental processes of mind activity, and the differentiation, as we have now seen, is sufficient to allow of a morbid diminution of moral control without any impairment—at any rate, recognised impairment—of those other combinations of mental processes which are involved in general intellectual development.

---

[2] Journal of Mental Science, July, 1885, p. 178.

[3] American Journal of Insanity, October, 1883.

[4] Journal of Mental Science, July, 1881.

So far, then, we have seen, not only that defect of moral control may be the result of congenital limitation of the capacity for its development by some morbid condition of the brain dating from antenatal life, but also that it may be due to arrest or delay of its development by physical disease occurring in infancy, and, further, that after there has already been considerable progress in its development it may be lost to a greater or less degree as the result of physical disease, particularly lesions of the brain and certain febrile conditions.

Defect of Moral Control as a Morbid Manifestation, without General Impairment of Intellect and without Physical Disease.

I turn now to the question whether similar morbid failure of moral control may not occur in children without any general impairment of intellect and without evidence of gross lesion of the brain or any more general physical disease. That moral alteration may occur as a symptom of insanity in adolescents and adults is well known, and the occurrence during adolescence of more limited psychoses affecting only the moral qualities has been pointed out by Dr Clouston. But the period to which I am referring is the period of childhood—which, if one includes infancy, extends from birth up to the age of puberty—and this, as I have already said, is the period in which moral control makes its first appearance and is gradually developed. At what age its development ceases it would be hard to say, but there can be no doubt that its most active development is in the period of childhood—from non-existence at birth up to a varying but large measure at puberty. No doubt in the years that follow puberty and which make up the period of adolescence with new and more permanent relations to environment moral control attains to a fuller degree, but its development at this period is rather the widening and strengthening of an already present function than the evolution of a new one as we see it in the infant and the young child. If, therefore, defect or delay may occur in the development of moral control apart from the associations which have been already considered it is in this earlier period that one would naturally look for its incidence. Moreover, if in adolescence instability of moral control is related to the growth and changing conditions of that function, as has been suggested, then *a fortiori* in childhood one would expect to meet with disturbances of the newly acquired function as well as failure in its development.

In considering deficiency of moral control in children apart from general impairment of intellect and apart from physical disease we are met at once by a grave difficulty. On what grounds are we to decide whether the lack of moral control is the manifestation of a morbid condition? As I have already pointed out, some range of variation is the natural outcome of differences of environment, using that term in its widest sense; but, granting this, we must also admit that with conditions of environment which are as closely as possible identical—for example, in children brought up in the same family with training and general influences apparently in every way similar—there are such wide variations in moral control as seem to point to some difference in the innate capacity for its development. Within certain limits such variation is arbitrarily recognised as normal; at any rate, it excites no suspicion of a morbid mental state, but there are certain children who show so marked a deficiency of moral control that even in large institutions containing some hundreds of children they can be picked out at once as different in this respect from all the others. This excessive degree of the defect, the outrageous character of its manifestations, is one point which, although insufficient as evidence of morbidity when taken by itself, may be important evidence when taken in conjunction with other facts.

A further point is the absence of any correspondence between the deficiency of moral control and the child's training and environment, even when allowance is made for the considerable range of variation which we arbitrarily recognise as normal at the particular age. For instance, when a boy of wealthy family, brought up by high-principled parents, surrounded with every care and refinement, and, moreover, liberally supplied with pocket-money, is expelled from school after school for petty thefts, as has happened in several cases either under my own observation or brought under my notice by others, this in itself is strongly suggestive of a morbid mental state which in almost all these cases is corroborated by other evidence to which I shall refer later. There is also another point in connexion with the manifestations of the moral defect which may have some bearing on the question of morbidity—namely, the oddity, if I may speak thus vaguely, of the child's misdoings in some cases. In his thieving, for instance, there is sometimes a handsome generosity; the child steals, but he does not want or keep for himself what he has stolen. one child pilfered repeatedly at school but on returning home would present his ill-gotten gains most dutifully to his mother, to her great distress. Or he steals but makes no use at all of the stolen property—his theft appears to be the gratification of mere acquisitiveness. Again, in their lying there is sometimes an apparent absence of any efficient motive, their lies are often picturesque inventions which remind one of the romancing which is sometimes shown by perfectly normal children during an earlier period of childhood (at about two to four years of age). I say "apparent absence," for no doubt there is always a motive, if only in self-aggrandisement. In the same connexion must be mentioned the extraordinary failure of punishment to have any deterrent effect in many of these children. In some of the cases to which I shall refer the child would commit the same misdemeanour within a few hours after punishment, although he had shown extreme fear at the time of punishment. The mother of one little girl (the child who showed permanent loss of moral control after scarlet fever) expressed this by saying that when the child was whipped "she seemed to mind it at the time but it never did her the same good it did the other children." But it is not merely to the exceptional degree of the moral defect, or to the unnatural character of the particular misdoing, that we must look for evidence of its morbid character; the antecedents, and, as later events show in some of the cases, the sequences of the lack of moral control, link it on almost indisputably to other morbid mental states. Family history throws no unimportant light on this condition, and the after-events in the career of these children, where it has been possible to trace them, should, I think, make us not merely "wise after the event" but capable of discriminating between those defects which are merely the result of faulty training and environment and those which are, indeed, the manifestation of a morbid condition. I shall refer more fully to these points in my third lecture and also to the very significant association of other psychoses and mental peculiarities with the moral deficiency in some of these children. A further indication of the morbid character of the defect which must also be considered and which is certainly sometimes of importance when taken in conjunction with those already mentioned is the presence of so-called "stigmata of degeneration." As we shall see, peculiarities of physical conformation are often associated with failure of moral control, as in other children they are associated with general impairment of intellect.

So far as my own experience goes the occurrence in children of defective moral control as a morbid condition, apart from general impairment of intellect and apart from physical disease, would appear to be by no means common. The facts and conclusions recorded here refer chiefly to 20 cases which have come under my own personal observation, but even this small number was collected partly by special effort to see such children. My observations have, however, been confirmed by comparison with the notes of a much larger number of unpublished cases, for the use of which I am deeply indebted to the kindness of Dr. Savage. In almost all these cases medical advice had been sought on account of the moral defect which had suggested to the parents or guardians that there must be some morbid mental condition. Of the 20 cases five were girls and 15 were boys, a disproportion which, I think, is not altogether accidental; at any rate, it would seem from recorded cases that boys are more frequently affected than are girls. The age at the time of observation varied from four years and eight months up to 13½ years. But there was a notable difference in the ages at which the manifestations of defective moral control had first attracted attention. In none of the cases was any such defect noticed until after the age of infancy (the end of the second year), but in three of them the child was noticed to be unusually troublesome through passionateness or spitefulness as early as the third year; in two cases nothing abnormal was noticed until the fifth year, in two probably in the sixth year, in two not until the eighth year, while in others this point was not ascertained. No doubt this difference in the dates assigned for the earliest manifestations is in some degree attributable to differences in capacity for observation on the part of the parents; moreover, one parent would not consider abnormal the early phenomena which to another were suggestive of mental disorder. But after full allowance has been made for these fallacies it seems clear that whilst in some cases the failure of normal control dates from very early in its development, in others an arrest of this development, or perhaps a loss of already acquired control, occurs at a later period of childhood.

The manifestations did not differ in character from those seen in the cases already considered. An extreme degree of passionateness was the most constant feature; but, as in the previous cases, there were in almost all the children other manifestations of defective moral control which will perhaps be shown most clearly by an account of some of the actual occurrences.

The cases fall, I think, naturally into two groups corresponding with differences in the date of the first manifestation of the morbid defect: (1) cases in which there is a morbid failure of the development of moral control; and (2) cases in which there is loss of already acquired moral control. These groups are, in fact, the counterpart of those which we have already considered, where the moral defect was associated in the one case with general impairment of intellect and in the other with physical disease.

Morbid failure of the development of moral control.—At first sight it might appear that the defect in such cases was necessarily congenital in origin, but the history in some of them strongly suggests that it is not always so; it would seem, indeed, that, as in idiocy and imbecility, while the defect may be due to a congenital limitation of the capacity for the particular development—moral in the cases under consideration, general intellectual in the idiot and imbecile—it may, on the other hand, be due to some morbid process occurring during infancy and arresting the development of moral control at a very early stage, as in other children it arrests the general intellectual development and leaves the child an idiot. A boy, aged five years and four months, was sent to me from an orphanage where he had been since the age of two and a half years. There he was thought to be different from all the other children in being of ungovernable temper; in his rage he would scratch and bite and scream. He was also very spiteful and seemed to take a delight in tormenting the other children; he sometimes took away their toys and threw them in the fire and then laughed at their grief, as the teacher said, "most hideously." He was also deceitful but had not been caught stealing. No animals were kept in the home so that there was little opportunity for the display of cruelty, but the other children had complained that he was cruel to such insect life as he could find in the garden. He was a very pleasing child to talk to, and the teacher said that he was "perfectly intelligent." His head measured 20¼ inches in maximum circumference—that is to say, it was slightly above the average; the forehead was narrow and low, there was a marked epicanthic fold, and his palate was rather narrow and high. The rest of his body was well formed. His sister, aged seven and a half years, was in the same institution and showed no abnormal moral defect. The father from his earliest years was extremely passionate, quarrelsome, and jealous; he killed the child's mother, and was then placed in a lunatic asylum. In this case the deficiency of moral control which was sufficient to mark the child as unique in an institution containing a very large number of children, together with certain, albeit slight, peculiarities of conformation, and the history of insanity in the father, all these are points which seemed to indicate that the condition was a morbid one; and judging from the very early date at which it was present (details of the child's life before two and a half years of age were not obtainable but are of no great importance as the morbid nature of a moral defect is, for the reasons already stated, hardly appreciable at so early an age), one seems justified in concluding that here there was a failure in the development of moral control, and the family history, with its suggestion of heredity, seems to point to a congenital limitation of the capacity for the development of moral control.

As another instance of this morbid failure of development I may quote the case of a boy who from a very early age, indeed almost from infancy, so the mother said, had shown a propensity for stealing. At first he would take food and articles of little value out of the cupboards, but since the age of seven years he had stolen money whenever he had had the opportunity. He was very untruthful and made every effort to conceal his thefts, hiding the stolen property in his boots or even in his stockings. This he had done again and again in spite of severe punishment. When sent on an errand he would appropriate part of the money and explain its absence by saying that there was no change or that he had lost it. When I saw him, at the age of nine years, he was filthy in his habits and frequently passed his fæces in his bed, not because of any morbid inability to control the sphincter, but because it was too cold, so he said, to get out of bed, which he refused to do. He seemed to have no shame whatever for his misdoings, and when caned for it took his punishment silently and sullenly, and no amount of punishment seemed to have any deterring effect. So far as school attainments go, he was reported by his schoolmaster to be an average boy, and there was nothing in the boy's appearance or in his conversation to suggest even the slightest degree of imbecility; but he had a furtive and sullen manner which I have noticed in other children with similar moral defect. On careful inquiry it was evident that in spite of his schoolmaster's testimony he had been backward in his earlier years, he had not learnt to walk until he was two years old, and he talked first at three years old. He had had convulsion twice at the age of 15 months, but none since. There wa difficulty in obtaining information as to the family histor except that the father had been a disreputable characte The boy had been brought up by his mother and step father, apparently with every care and endeavour to trai him properly. There seemed to be nothing in the boy's environment to account for his lack of moral control; the father had deserted the mother shortly after the child was born, so that the influence of his example could be excluded.

The next two cases which I shall mention may illustrate the morbid failure of moral development as the result of its arrest by some cerebral disturbance in early infancy. A girl, now aged 13½ years, had been unruly and difficult to manage from her earliest years; she seemed to be lacking in natural affection for her mother, she was untruthful, and she had stolen money which she used for herself. She seemed to have very little idea of obedience and at school was the plague of her teachers. She was sometimes wantonly filthy; for instance, one day she amused herself by spitting all over a shop window; she would expose herself indecently in the streets and was always "running after" the opposite sex, and on at least one occasion was said to have encouraged one of them to indecent or immoral practices with her. This child was slow and backward at school; she seemed to lack power of attention, although the schoolmistress said that she was "quite teachable" otherwise; except in her backwardness at school she might pass for a normal child. This was a tall girl with a dull expression; she had a very narrow frontal region; the maximum circumference of the head was 21⅛ inches; the palate was very high and narrow. She had never had convulsions, but birth was instrumental and very difficult, the establishment of respiration was much delayed, and there was still evidence of the difficult parturition in very slight weakness of the left arm which had apparently shown Erb's paralysis up to the age of four years. Whilst, however, the asphyxia seemed to be a probable cause for the morbid mental state it was noteworthy that the child's father was of feeble intellect and deserted the mother before the child was born.

Another child, a boy, aged five years, was brought to me with the history that he had been unusually spiteful from the age of two years; he would bite his mother and strike anyone with a stick in wanton spitefulness, a few days before he was brought to me he had thrown a glass at a child and cut its hand severely He was also extremely passionate, for instance, on two occasions when put out of the room for being naughty he had taken up a stone and flung it through the window He frequently stole, after having a good meal he would steal food out of the cupboards, he would also steal purses and hide them, but he did not use the money He was said to be very quick at school. He read small words well, knew "twice times" perfectly, and seemed to be quite up to the average in ordinary intellectual attainments, and in this respect passed for a normal child. He was, however, curiously distrait, for instance in saying "Good night' he went round the family five times one night, apparently not noticing that he had said it before, and he had done the same with his prayers. He showed also a curious perversion of appetite, almost amounting to "pica," to which I shall refer again in my last lecture. There was no history of insanity in the family, but the child had had a large number of convulsions, together with some illness which was called "compression of the brain," between one month and four months of age. He was rather late in learning to walk (he began at one year and 10 months) and also in learning to talk which he began at two years. His head measured 20¼ inches in maximum circumference—that is, about three-quarters of an inch above the average for the age. This child could not have been called backward in school attainments, there was no general intellectual impairment but none the less the peculiarities to which I have referred pointed to an abnormal mental condition underlying the failure of moral control and the history of severe cerebral disturbance in early infancy suggests that the moral development had been arrested thereby

Loss of already acquired moral control—In this second group, as I have said, the earliest manifestations of moral defect appear at an age when some considerable progress has already been made in the development of moral control the child who has hitherto been a normally well behaved, perhaps an exemplary child, shows an unaccountable change of character, the good tempered, tractable child becomes violently passionate and unruly, the truthful and honest child seems to have lost all sense of honesty, and natural affection seems to have disappeared And here, again I would point out that this group probably includes cases which are not altogether similar in character—at any rate, they differ markedly in the course which they run, for whilst in one case the loss of moral control appears to be permanent, if one may judge from a duration of years, in another it lasts only a few weeks or months, and in a third, as I shall show, it would seem to be a recurrent disorder Whether in any of these cases moral control is fully up to the average standard before the defect attracts attention may be doubtful, but it is clear that the manifestations to which I refer are in marked contrast with the child's previous behaviour

A boy, aged nine and a half years, has been under my care for the past 12 months. Up to the age of seven years and one month he was a very obedient, well behaved child but he was said to have been always rather bad tempered He learnt to walk at 18 months, and talked well at two years. He had convulsions repeatedly at the age of 10 months but otherwise he was thought to be a perfectly healthy child until the onset of the present condition Just after the age of seven years he seemed to alter altogether; he became extremely disobedient, taking little or no notice of commands. He was very self willed, for instance, on receiving a new hat he refused to wear his old one and, rather than do so, disposed of it altogether, the mother thinks, by burning it, and if he did not like his clothes he would tear them to pieces. He showed also an unnatural cruelty, he was found one day cutting up a rabbit alive with scissors and was already, so the mother said, "smothered in blood." At another time he was found beating chickens with a stick, taken to Sunday school he was so outrageously unruly and quarrelsome that he had not been allowed to go again, and at day school he was a continual trouble. For some time past he had pilfered small articles at home and quite recently he had stolen half a-crown from his mother On being taxed with these and other misdemeanours he denied them flatly and on being driven into a corner, so to speak, invented the most plausible tales to account for them. Although extremely frightened by corporal punishment he would commit the very same offence almost directly afterwards. When I first saw him he would smear his fæces about the wall of the water closet and sometimes about his bed, but he had not done this recently With this history one might expect to see a child of obviously defective intellect, if not an actual idiot, but the facts are far otherwise. He is a bright, attractive little fellow with a pleasing face, his conversation also is bright and intelligent, he is backward in school attainments but his attendance has been very irregular and he shows that lack of attention which is very noticeable in many of these cases and which no doubt accounts to a considerable extent for backwardness in school acquirements. In such a case the degree and persistence of the moral deficiency as shown in the manifestations which I have described, and also the contrast between the present and the previous condition without any apparent explanation in changed influences or environment—these alone might warrant us in regarding the loss of moral control as the manifestation of a morbid mental state, but here there is confirmatory evidence in the family history the child's maternal grandfather attempted suicide three times, his great grandfather was thought to have done the same, the paternal grandfather is now insane, and the mother's uncle died in a lunatic asylum. The boy shows no "stigmata of degeneration" unless the unusual size of the head be considered as such, in its maximum circumference it measured 21⅜ inches at the age of eight years and three months. I may add that before this boy came to me he had been seen by three medical men all of whom were, quite independently of each other I believe of opinion that, owing to his cruel and dangerous propensities he ought to be placed under restraint in some asylum

Another boy was brought to me at the age of five years with a history that for two months he had been very excitable and had at the same time become extremely spiteful, throwing things at people apparently in wanton spitefulness and attacking strange children in the street without any provocation, he had expressed a wish one day to "chop his mother's head off with a chopper, and was caught one day in the act of putting the cat into the fire, and on a subsequent occasion he attempted to put it into a copper of boiling water I saw this boy 18 months later when he was said still to be very excitable and extremely passionate, kicking or striking anyone who offended him Nine months previously he had hit his mother on the head with a big toy gun because he could not have some trifling thing that he wanted, he was also said to be spiteful to other children. He was untruthful, but his lying was of the purely romantic type, so much so that it was difficult to imagine that the boy intended to deceive His head was unusually large, measuring 21⅛ inches in maximum circumference at the age of six and a half years He is a heavy looking but well grown boy and he is fully up to the average in school attainments. His maternal grandfather had diabetes one maternal uncle attempted suicide twice and two other maternal uncles have become confirmed drunkards. The boy's parents are respectable middle-class people and seemed to give the child excellent care

Of course without watching such a case for a much longer period one could not be certain that the condition was permanent, but its already long duration with very little improvement suggests that it is so The same doubt must attach to the case of a boy aged five years and 10 months who was brought to me on account of persistent stealing and lying Nothing of the kind had occurred until about five months previously when he brought home two door keys and said that he had found them. It was proved that he had taken them out of the doors at school He was severely punished but three weeks later he brought home an inkpot which he presented to his mother, saying that he had found it, this also had been stolen out of a school cupboard Soon after this he stole a chain from one of his schoolfellows, and when suspicion was aroused by it at home he invented a plausible tale of receiving it in exchange. The stealing had become so frequent when I saw him that it was necessary to search him daily before he left school The parents were much distressed and had evidently taken unusual pains to train the child aright. The boy seemed perfectly bright and intelligent but he had only learnt to walk at 21 months and did not talk until he was two and a half years old, and then only said single words There was no family history of insanity or neurosis and the boy showed no "stigmata of degeneration"

In other cases the subsequent history has shown that the loss of moral control was temporary. For instance, in a girl, aged four years and three months, nothing abnormal was noticed until the age of four years and then almost suddenly she became so passionate that she was brought to the Children's Hospital with the idea that there must be some mental disorder. The least thwarting of her wishes would produce an outburst of rage in which she would tear her clothes and fling china or anything near down upon the ground, and she would scratch or bite anyone who offended her. Sometimes in her rage she would bang her head against anything near and twice she had been sent home from school for fear she should injure herself. These manifestations lasted for nearly four months and then ceased. She is now, five years later, not a good-tempered child but she shows no abnormal defect of moral control. She is fully up to the average in school attainments; but her palate is extremely high and narrow and she shows marked fidgety, almost choreiform, movements such as Dr. Warner called "microkinesis"; the mother is also a very nervous woman and says that she has frequent twitchings in her limbs and face; the child's brother has recurrent outbursts of rage and excitement to which I shall refer in my next lecture. There was no insanity in the family.

Another child, a boy, aged four years and two months, was brought to the hospital because he had recently changed in disposition; he seemed to have lost all sense of obedience, so as to be almost unmanageable; he was restless and he was also spiteful. He showed at the same time an interesting association in a temporary diurnal incontinence of fæces—a condition which, as is well known, occurs specially in children of unstable nervous equilibrium. After a few weeks the lawlessness and spitefulness were much less marked and then very quickly disappeared; there had been no recurrence when I heard of the child again two years later.

It would seem, then, from clinical evidence, that, as was suggested by the lack of any constant proportion between general intellectual and moral defect in imbeciles, a morbid defect of moral control may occur apart from any general impairment of intellect. The possibility of such an occurrence was confirmed by the relation of moral defect to physical disease in certain cases where there was no general impairment of intellect. We have considered, also, the occurrence of a morbid defect of moral control apart from obvious physical disease, and we have seen that we can recognise in children both a morbid failure in the development of moral control and also a morbid loss of already acquired moral control. In my next lecture I shall mention a further variety of these manifestations, and consider more fully some of the grounds upon which these defects are regarded as morbid

The Lumleian Lectures

ON

THE COMPREHENSIVE STUDY OF THORACIC PHTHISIS.

Delivered before the Royal College of Physicians of London on March 13th, 18th, and 20th, 1902,

BY F. T. ROBERTS, M.D., F.R.C.P. LOND.,
HOLME PROFESSOR OF CLINICAL MEDICINE AT UNIVERSITY COLLEGE; SENIOR PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL; CONSULTING PHYSICIAN TO BROMPTON CONSUMPTION HOSPITAL, ETC.

LECTURE III.[1]

Delivered on March 20th 1902.

III.—CLINICAL HISTORY AND INVESTIGATION.

MR. PRESIDENT AND GENTLEMEN,—The clinical aspect of thoracic phthisis opens up a very wide field, but here again I must confine myself to the discussion of my subject on very general lines. An intelligent conception of the clinical history and manifestations of thoracic phthisis can only be founded on a fairly comprehensive and systematic knowledge of the pathological conditions which have been dealt with in the preceding lecture and of their effects. Moreover, for the practical investigation of individual cases it is essential that the observer should have had an adequate training in the study of symptoms as well as in, at any rate, the ordinary skilled methods of examination, the application of which is absolutely necessary in order to form a positive and reliable diagnosis. I venture to remind the modern medical student that the ability to investigate, or what may be termed the "art of examination," even in a common case of "consumption," is not acquired or mastered in a day or without intelligent effort on his part and the more personal experience which he has enjoyed in relation to these cases the more competent and capable will he become to recognise and understand them in practice. To anyone thus qualified there ought to be little or no difficulty in dealing with the large majority of such cases from the diagnostic point of view or in estimating the significance of all the important clinical facts which may be noted. But to suppose that any uneducated, untrained, and ignorant impostor who claims to have discovered a "cure for consumption" is in the least degree competent to determine or to comprehend the conditions with which he is dealing is obviously most absurd and preposterous.

Cases of thoracic phthisis come before the practitioner under very different aspects and, assuming that he has the requisite knowledge and skill, there are certain general principles in dealing with them which need to be strenuously urged at the present day. In the first place, as we are all now so eager to detect the disease in the very early stage, with the view of arresting and curing it, it follows that we cannot be too much on the alert in watching for it when it is not definitely revealed or known to exist, especially under circumstances in which its advent is not improbable. From this point of view there is no excuse for ignoring or neglecting suspicious symptoms, however slight; and it is highly desirable to impress upon the community generally this important principle, for undoubtedly patients themselves are often to blame in this matter. If an individual is known to have had an attack of pleurisy with effusion or pneumonia particular attention should be paid to the case, and it would be well as a precautionary measure to examine the chest from time to time even if there are no symptoms. It cannot be doubted that from a neglect of this practice a large number of cases of phthisis have made considerable progress before the mischief is discovered, the disease having by that time gained a firm hold upon the lungs or other structures. Secondly, it is necessary to be always prepared for cases which do not fall in with the usual conception of phthisis, especially those of a more acute nature, as otherwise very serious mistakes in diagnosis are liable to be made. Thirdly, when a case of recognised thoracic phthisis comes under the care of the practitioner he *should never* deal with it in an offhand and casual way but should take the trouble to study it clinically in all its aspects and to try to understand the actual conditions with which he has to deal within practical and rational limits. If this were done more generally and as a matter of routine I venture to say that treatment would be founded on a much more definite and sound basis than it often is at the present time.

The clinical study of thoracic phthisis naturally presents itself under the three divisions of: *A.*—Mode of onset or manifestation; *B.*—Personal clinical investigation; and *C.*—Course and terminations. I now proceed to deal, so far as time permits, with these several aspects of the subject in turn.

A.—MODE OF ONSET OR MANIFESTATION.

Under this head I desire to indicate not only how thoracic phthisis may actually begin but in what ways it may be manifested in ordinary practice. Excluding cases originating under special and exceptional circumstances, the modes in which the complaint may be revealed clinically are as follows:—

1. With a *sudden*, more or less grave, symptom or lesion. Hæmoptysis and pneumothorax are the important events to be noted under this head, and especially the former, which is by no means uncommon. Their relation to phthisical changes has already been considered, and it will suffice to remark here that either of them may be the first definite manifestation of the existence of phthisis, quite apart from the fact that the practitioner may be called in to a case in which the disease is known to be present, though he is personally altogether unacquainted with the previous conditions. Under these circumstances it may be inexpedient to attempt, or

---

[1] Lectures I. and II. were published in THE LANCET of March 29th (p. 867) and April 5th (p. 937), 1902, respectively.

impossible to arrive at, anything like accurate or complete diagnosis, but the possibility of pneumothorax should always be borne in mind.

2. As an *acute* or *subacute* illness definitely associated with the chest, though not always entirely confined to this region. Moreover, the thoracic changes may be secondary to some other affection, such as influenza, measles, or whooping-cough. Cases coming under this category are by no means uncommon and they may be briefly indicated as follows:—(*a*) Those which are merely a part of *general acute miliary tuberculosis* Here the pleuræ and pericardium as well as the lungs may be involved (*b*) *Acute miliary tuberculosis limited to the lungs*, it may be to one lung, associated with an old general pleuritic adhesion, of which I have met with a very interesting example (*c*) Cases of an *ordinary pneumonic* type, involving a lobe or an entire lung, or even both organs The consolidation as a rule breaks down rapidly but in some instances it remains as a more or less chronic condition, ultimately becoming disorganised, though occasionally most of it clears up I have a strong impression that a certain proportion of the rapidly destructive and fatal cases of acute pneumonia which are so disturbing nowadays are really tuberculous, and I have met with some such cases in which I could without doubt associate the condition with previous unrecognised chronic phthisical lesions. On the other hand, it is important to note that pneumonia occurring in a case of definite or even pronounced phthisis may end in recovery. There is rather a prevalent idea, I believe, that apical pneumonia is always tuberculous, but judging by the satisfactory results in several cases which have come under my observation I do not think that there is any real foundation for this notion (*d*) Cases of a *broncho-pneumonic* or *catarrhal pneumonic* type, combined with more or less diffuse tubercle, followed by rapid caseation and destruction of the pulmonary tissues. These cases are of much more common occurrence and form the larger proportion of those recognised as "galloping consumption" Both lungs are usually affected, either from the first or very speedily This form is not uncommon in children, especially after measles or whooping-cough, but it also occurs in adults and follows hæmorrhage in many instances (*e*) Cases which appear as *pleurisy*, sometimes with extensive and diffused patches of lymph-exudation and of a "dry" type, but as a rule with more or less abundant effusion. The more typical cases of tuberculous pleurisy with effusion often present striking features which cannot be overlooked They may come on in quite a latent manner without any prominent symptoms, but this is by no means always the case Usually the fluid increases steadily and shows no indication of absorption, while it tends to return again and again after removal by operation. The fluid is usually sero fibrinous, sometimes hæmorrhagic, but may be purulent, or becomes so later on. In some instances the pleurisy is bilateral or one side is attacked after the other As I have previously stated, the fluid in undoubted cases of tuberculous pleurisy is sometimes absorbed sooner or later, adhesions being subsequently formed. (*f*) Cases of a *mixed* character, in which both lung and pleura are involved in various degrees, the pulmonary lesions being either obviously pneumonic, or tuberculous, or both. This group of cases is quite definite and I have met with several instances. Possibly the pericardium may be implicated, but I cannot speak positively on this point from personal observation

3. As a *primary and independent chronic disease* of the lung and adjacent pleura in the large majority of cases beginning near the apex on one or both sides, and tending to progress in a downward direction, but usually slowly and often insidiously This is frequently accompanied with catarrh of the main air tube, or even some degree of bronchitis, or occasionally there is an asthmatic tendency. The symptoms are generally attributed to a "bad cold" or "cold upon cold" The changes may or may not be detected at an early period, but the mischief has often made considerable progress before it is discovered. The ordinary run of cases of thoracic phthisis belong to this category

4 As a *primary laryngeal tuberculosis* with prominent local symptoms and objective manifestations, followed by implication of the lungs and other thoracic structures. Sometimes the disease declares itself in both larynx and lung from an early period, so that it may be impossible to determine exactly where it started.

5 As a *complication* upon some previous morbid conditions affecting the chest which have been known to exist and are not uncommonly pronounced. Under this category I would draw special attention to cases of phthisis following prolonged chronic bronchitis, either alone or accompanied with emphysema; plastic bronchitis; extensive pleural adhesion or other remains of pleurisy; some forms of fibrotic lung; syphilitic lesions; and aneurysm. In the pleural cases the phthisical lesions often develop at quite a remote period after one or more definite attacks of pleurisy or pneumonia, which may have been entirely forgotten unless careful inquiry elicits a history of their occurrence. There may, however, be no history of such an attack and yet the adherent pleura is obvious enough. The phthisical changes which supervene in this group are generally chronic in their development, but sometimes an acute phthisis is set up.

6. As a *primary glandular affection* in the mediastinum, with obvious clinical signs, afterwards invading the lungs or other structures. This class of case is chiefly met with in children

7 As a *secondary manifestation of tuberculous disease*, either acute or chronic, in cases where similar mischief is known to exist in other structures, altogether remote from the chest.

8. As a *complication* in the course of one or other of the general or non-tuberculous local complaints with which thoracic phthisis is known to be associated Of these diabetes is a fairly typical example.

B—PERSONAL CLINICAL INVESTIGATION

I propose under this heading to give a general outline of the course of procedure which may be called for in the clinical investigation of a case of thoracic phthisis, and of the phenomena to be studied What may actually be required in individual instances will depend upon circumstances, and the practitioner must be guided in this matter by his knowledge, practical training, and experience, aided by intelligent judgment and common-sense. It cannot be too strongly insisted upon at the present day that the rational, and indeed essential, investigation of a case of thoracic phthisis involves a great deal more than the examination of sputum for tubercle bacilli, or the employment of other scientific modern methods which threaten to supplant the teaching and experience of the past. There are certain parts of the investigation which ought never to be omitted or neglected, while others are only required under particular circumstances.

Taking, then, a comprehensive survey of what may be termed the stages of clinical investigation for purposes of diagnosis which may be called for or which have been advocated in dealing with cases of thoracic phthisis, they may be thus enumerated 1. The observation and study of symptoms—symptomatology 2. Physical examination of the chest and its vicinity by the ordinary simple methods 3. Examination by special instruments or apparatus 4 Skilled examination of the sputum or expectoration 5 Examination of the throat and main air-passage, including laryngoscopy 6. Removal of fluid from the pleural cavity, or possibly of other morbid products from the chest, either for general examination or for further scientific investigation. 7 Inoculation with tuberculin. 8. Agglutination-test. 9 The use of the Roentgen rays. I will now discuss these several stages in the order in which they have been enumerated

1.—*Symptomatology*

The observation and study of the phenomena which in ordinary language we term "symptoms" is of the highest importance in relation to thoracic phthisis from different points of view Although in doing so I must necessarily be going over ground which is perfectly familiar to any well-informed medical practitioner I should hardly do justice to my subject if I did not indicate briefly the nature of these phenomena, and I trust, therefore, that I may be excused if I appear to trouble you with information which is needless and unworthy of the occasion. The symptoms may be primarily grouped under the following heads: (1) local, associated with the chest and upper air-passages; (2) general or constitutional, affecting the entire system more or less; (3) symptoms connected with the digestive organs; (4) symptoms resulting from tuberculosis of other structures remote from the chest and respiratory apparatus; (5) symptoms due to some general or local disease to which the phthisical condition is secondary, (6) symptoms associated with various complications, non tuberculous but related to the phthisis, or it may be quite accidental and independent; and (7) mental symptoms The individual phenomena coming under these several groups present themselves in various degrees and combinations in different cases, and I now proceed to enumerate them.

1. The more common *local* symptoms include painful or other morbid sensations associated with the chest or air-passages; disorders of respiration of different kinds; cough; materials discharged as expectoration; hæmoptysis; and changes in the voice—especially huskiness or hoarseness, In certain conditions or exceptional cases there may be a troublesome welling-up of secretion from the air-passages which has to be cleared away by voluntary effort when it reaches the throat; obvious wheezy or other noisy sounds during breathing; a foul smell of the breath, or more particularly of the expired air after a cough; certain pressure symptoms; marked disturbance of the cardiac action, apart from mere change in its frequency and strength; or dysphagia.

2. Under *general* symptoms may be first noted any original delicacy of the individual, or the signs of a distinct tuberculous or strumous diathesis. The other chief phenomena are mere increase in temperature or pyrexia, as determined by the clinical thermometer; definite fever or febrile paroxysms, often accompanied with chilliness or actual rigors and of a hectic type, it may be accompanied with the "hectic flush"; a rapid pulse, with changes in its characters; wasting, culminating in positive emaciation, which may be extreme; anæmia, which may be a prominent early symptom; excessive sweating, often profuse, especially during the night, or rather in the early morning, or with sleep at any time, generally associated with fever; and subjective sensations of languor, fatigue on slight exertion, more or less weakness, exhaustion, or actual prostration and helplessness. Cessation of menstruation may be regarded as a symptom of general significance in some cases. A certain degree of œdema of the legs is not uncommon, apart from dropsy due to complications. Cyanosis is marked in certain acute cases, but is quite exceptional in uncomplicated chronic phthisis. Sometimes the skin is abnormally dry as well as hot, or the palms and soles burn. In advanced cases there are various general symptoms indicating profound failure of nutrition of all the structures, and these may be very pronounced in connexion with the skin, hair, nails, &c. At this period, also, the temperature often falls below normal, and there may ultimately be a condition of more or less collapse. Some writers attach special importance to certain particular symptoms as connected with phthisis, but even when present they only occur in well-marked cases and are of little, if any, significance. The characters of the urine vary considerably, and nothing definite can be said on this point.

3. Symptoms connected with the *digestive system* are of great importance in relation to thoracic phthisis and should always receive special attention. They may be pronounced at a very early period, even before there are any indications of chest trouble, but I must say I have not met with many cases presenting the definite "gastric onset" described by some writers or any particular form of dyspepsia. The symptoms to be particularly noted are impairment or loss of appetite, which may amount to total anorexia and entire aversion to food; thirst not uncommonly; a furred or red and irritable tongue and unhealthy condition of the mouth; nausea and tendency to sickness, or actual vomiting, especially after cough, though in some cases quite independent of this act; dyspeptic symptoms, such as acidity or flatulence; and constipation as a rule. The breath is also often peculiarly unpleasant. The red line which is sometimes observed on the gums in advanced cases is by no means peculiar to phthisis. It is a remarkable fact that even in acute or extensive chronic phthisis in its later stages there may be no gastric symptoms whatever, the patient enjoying his food thoroughly and digesting it without any difficulty.

4 The symptoms due to *tuberculosis affecting other structures* vary, of course, with the seat of the trouble, and they are sometimes decidedly complicated. Among the chief structures which are likely to be involved it will suffice to mention the mouth and throat, the intestines, the peritoneum, the absorbent glands, the urinary organs, the genital system in the male or female, and the central nervous system.

5 and 6. The phenomena coming under these groups and which are either associated with diseases preceding the phthisical condition, or with morbid changes occurring as complications during its progress, also necessarily differ in different cases, and I only allude to them in order to remark that they should always be borne in mind and duly recognised when present in individual instances.

7. As regards mental symptoms, it will suffice to note that they may be pronounced in acute phthisical cases and at the termination of chronic cases.

General remarks.—It is obviously quite out of the question to attempt any discussion of individual symptoms in these lectures, though I have notes of many practical points which I should have liked to refer to. I must content myself with offering a few general observations in relation to this part of my subject.

1. The frequent development of thoracic phthisis without any definite local symptoms for a variable period must always be borne in mind. Even in acute cases they may be practically absent for some time or throughout, while general symptoms are pronounced but are misunderstood. It is in the more chronic forms of the disease, however, that its development with little or no local symptomatic manifestations must be particularly remembered in order to avoid errors in diagnosis. There may be literally no symptoms whatever. Not uncommonly, however, slight symptoms are present, such as a hacking dry cough, slight shortness of breath, or huskiness, but they are thought to be of no consequence and it may be a considerable time before they excite any actual alarm, when it is found on examination that the mischief has gained a firm hold. Patients often attach much more importance to localised pain or tenderness and still more to the faintest suspicion of blood; but while these phenomena should always receive adequate attention they are really often of far less significance than those just mentioned. Pronounced tenderness or hyperæsthesia over the apical region of a lung should, however, never be disregarded. In these early cases without prominent local symptoms the careful observation and study of phenomena of a general nature may be of the utmost diagnostic service, as well as of symptoms connected with the alimentary canal and menstrual disorders in young females.

There is another class of case where the onset of thoracic phthisis is liable to be overlooked from a symptomatic point of view—namely, when the patient has suffered from chronic bronchitis, giving rise to more or less constant or frequent cough and expectoration; or when such symptoms occur habitually in the morning in connexion with catarrh of the throat and upper air-passage, usually traceable to definite causes. A similar difficulty may arise in asthmatic cases. Here, again, the study of general symptoms is highly important from a diagnostic point of view.

2. In definite cases of thoracic phthisis symptoms are, as a rule, more or less pronounced, and in most instances they can be recognised with little or no trouble, being often, indeed, but too evident. Still, it cannot be too strongly insisted upon that it is not sufficient merely to enumerate them casually, and that they ought always to be adequately inquired about or personally observed and investigated, so far as is practicable. I feel sure that there is far too much neglect in this direction, most cases being dealt with in a very summary fashion as regards their symptomatology, to the detriment of the patient in many ways. With respect to local symptoms it is highly important that they should be intelligently studied individually, in their mutual bearings, and in relation to the actual thoracic conditions which exist, as determined by physical and other methods of investigation. I particularly wish to draw attention to the diagnostic value of sputum as a mere symptom and also to the indications afforded by disorders of respiration. With regard to hæmoptysis there is, I have reason to know, an exaggerated impression even amongst members of the profession as to its supposed essential relation to phthisis. As a matter of fact it is absent in a considerable percentage of cases from first to last. Among the general symptoms, in the determination of the bodily temperature and weight of the patient the clinical thermometer and weighing-machine should be systematically employed, when obviously required and when circumstances permit. I cannot enter into any details here on this point, but investigation as regards pyrexia is highly important and some observers advocate that the temperature should always be taken in the rectum.

3. As regards the actual symptoms associated with thoracic phthisis we have to be prepared to meet with great diversity in their exact nature, severity, and combinations; while they often change markedly during the progress of the complaint should it be prolonged. Things are not

uncommonly very complicated in this respect, giving rise to much difficulty in treatment.

4. The study of certain individual symptoms is of the highest interest in connexion with the general subject of thoracic phthisis as well as in not a few individual cases. To these, however, I cannot now refer more particularly.

2.—*Physical Examination.*

Notwithstanding the advances which have been made in the scientific clinical study and diagnosis of thoracic phthisis, in my opinion physical examination of the chest still holds its own, and it is the greatest possible mistake to attempt to minimise its value or even to suggest to the rising and future generations of the medical profession that any other method of investigation can take its place in ordinary practice. Such examination is always immediately available, and I have no hesitation in affirming that if it were carried out more as a routine practice when there are any suspicious symptoms of phthisis, whether local or general, or more often both, and in cases of neglected cough, an early and positive diagnosis would be made much more frequently than is the case at present. But to be of any reliable service it must be performed on rational, comprehensive, and systematic lines, with some intelligent conception of the purposes for which it is intended. The actual course of procedure will have to be modified according to circumstances, and in dealing with acute or advanced cases of thoracic phthisis the examination must be particularly conducted with due regard to the condition of the patient so as to guard against unnecessary disturbance or positive injury.

At the outset it is desirable to recognise clearly the purposes which physical examination of the chest has in view in relation to thoracic phthisis and they may be thus summarised: (1) to recognise the mere presence of pulmonary tuberculosis, especially in its earlier stages; (2) to determine the extent of the mischief in the lungs and whether it is unilateral or bilateral; (3) to find out whether other thoracic structures are involved in any way and which; (4) to make out as definitely as possible what are the actual conditions present, both pulmonary and extra-pulmonary; and (5) to watch the progress of the disease in the lungs, especially when of an active type, and to be on the look-out for the development of acute or accidental complications or for other organic changes of a more chronic nature which may be of more or less importance.

Outline of the course of examination.—I propose now to give a sketch of the mode of procedure which may be conveniently followed in the physical examination of phthisical cases under ordinary circumstances, and to call attention to certain points which I think worthy of special notice.

A. It cannot be too strongly insisted upon that for several reasons the examination should always in the first instance include the whole chest, and it is often a source of serious error to confine it to the regions of the apices, on the supposition that the phthisical lesions always begin there. If there be no reason to the contrary the plan I habitually adopt is to get a comprehensive view for a moment of the stripped thorax; then, covering it with some suitable garment, to carry out further examination more leisurely, without needless exposure, of which not a few patients or their friends have an intense dread. When examining the upper thorax it is most important, not merely to study the apices in front, but also the supra-spinous and interscapular regions posteriorly, where the signs are not uncommonly well-marked when absent or indefinite anteriorly. Attention should also be paid to the supra-clavicular as well as to the infra-clavicular spaces and when percussing to the clavicular region. Moreover, when comparing the apices it must not be forgotten that both may be affected and the want of contrast in the signs may be decidedly misleading. Of course, the disease may possibly start in other regions or be disseminated, and this fact should always be borne in mind when examining the thorax for phthisis. The extent of the mischief can obviously be determined only by a comprehensive investigation of the entire region.

B. The four ordinary methods of physical examination—namely, inspection, palpation, percussion, and auscultation—should be thoroughly and efficiently made use of for the recognised purposes for which they are severally intended. I feel sure that the two simpler methods first mentioned are not employed systematically to anything like the extent that they ought to be and thus important diagnostic factors are lost sight of. Of course, percussion and auscultation afford the more definite and positive signs of phthisical and associated lesions and these always demand careful study. I dare say that auscultatory percussion may be useful sometimes but I cannot affirm that I have found it necessary to avail myself of its help. Under special circumstances we may elicit the "bell-sound" or bring out "succussion signs" in cases of thoracic phthisis, mainly, of course, in relation to pneumothorax and its accompaniments. For a practical plan of investigating and recording physical signs in connexion with the chest, which I think may be useful as a basis and guide in dealing with cases of thoracic phthisis, I venture to refer you to an article which I contributed to the *Edinburgh Medical Journal* in 1898 on "The Systematic Physical Examination of the Chest."

C. In the very early stage of pulmonary phthisis of a definitely tuberculous nature, involving the vicinity of the apex of a lung, examination has to be made with special care, behind as well as in front, and due weight must be given, not to any one sign, but to a combination of slight signs. It is necessary here, however, to warn against mistaking an apical adhesion for early phthisis. Even when tuberculosis actually exists physical signs are by no means always so definite at a first examination as to enable a positive diagnosis to be made, though I must say that sufficiently characteristic phenomena are sometimes not detected or duly appreciated from want of experience or of adequate examination. *Under these circumstances repetition of the* examination is obviously called for—it may be several times at short intervals—in cases which still give occasion for suspicion or anxiety, or where an apical adhesion exists. There are not a few cases of supposed phthisis in which the investigation shows at once and conclusively that there is nothing whatever the matter, so that it may be of negative as well as positive diagnostic value. As a matter of course, repeated examination is necessary at intervals, varying according to the nature of the case, when it is desirable to watch the progress of the lesions in definitely recognised phthisis.

D. The manifest purposes for which physical examination is intended in relation to thoracic phthisis are to recognise and to study the pathological conditions which I have previously discussed so far as they are revealed by physical signs. It may be well if I endeavour to explain briefly the practical application of the several methods from this point of view, and to indicate the course of procedure which may be conveniently followed as a matter of routine.

1. Particular attention should invariably be first paid to the *superficial structures*, especially to determine whether there is wasting and its degree, taking also into account the mammary glands. Should there be marked emaciation due allowance must be made for this condition in the further investigation, else serious mistakes in diagnosis are liable to be made. It must not be supposed, however, that these tissues are always atrophied in cases of phthisis, for the chest may be well covered even when there is extensive disease within. Any enlargement of veins or venules, glandular or other external evidences of tuberculosis, subcutaneous emphysema, or other superficial conditions should be noted and are hardly likely to be overlooked by an ordinarily careful observer.

2. It is always desirable to endeavour to make out what has been the *original state of the thorax* as regards conformation and capacity, independent of any changes due to actual phthisis. An abnormally small and contracted chest, inherent to the individual, is always a disadvantage, whether of the elongated and narrow or flattened type, or both, which is most common. In some instances it may be observed that the thorax has been unduly distended previously to the development of phthisis, and therefore a large chest must not always be regarded as a favourable indication.

3. Any preceding *deformity* must be duly noted and an endeavour made to understand its nature and origin and how far it interferes with the capacity of the chest or with its contents. When pronounced it is not likely to be overlooked, but the slighter malformations, such as pigeon-breast or rickety thorax, by no means always receive the attention they deserve. The changes in the shape and size of the thorax resulting from the intra-thoracic phthisical lesions constitute one class of definite signs of the complaint, and must be studied systematically from that point of view.

4. The next step is to determine the *degree of mobility of the thoracic framework*, which is more or less diminished in many cases of phthisis, and the chest may be absolutely rigid

and fixed. This difficulty is of much consequence in not a few instances, and I desire to emphasise the necessity of recognising it and endeavouring to estimate its degree as a matter of routine in cases of this nature, but particularly in those of a very chronic type and in elderly persons.

5. Abnormal physical conditions of one kind or another associated with the *pleura* are present in practically all cases of thoracic phthisis and should always be systematically looked for. They include morbid states of the surfaces, due to dry pleurisy or to tubercle; fluid effusions of different kinds; adhesions, varying in extent, often with more or less thickening; and the presence of gas or of gas and fluid in the pleural sac. Most of these are likely to attract attention when present and their signs are as a rule sufficiently characteristic. I must again, however, emphasise the necessity of always remembering pleuritic adhesions and endeavouring not only to recognise their existence but to estimate their effects in a particular case. It must also be borne in mind that the conditions mentioned may be variously combined and the physical signs are then sometimes difficult to understand.

6. The changes in the *lungs* are, of course, the most important to be studied by physical examination as a rule, and so far as the phthisical process is concerned they are practically of four kinds—namely: (1) primary consolidation, tuberculous or pneumonic, or both; (2) softening and breaking down of this consolidation; (3) cavities or vomicæ, presenting considerable varieties, with corresponding differences in the physical signs; and (4) fibrosis, giving rise to more or less dense induration and having peculiar signs of its own. In addition to these conditions, however, we have to bear in mind others which are so often associated with the more pronounced phthisical lesions, especially bronchitis, distension of portions of lung or true emphysema, pulmonary collapse in parts, bronchiectasis, and hæmorrhage or its remains.

It is altogether outside my purpose to describe the physical signs of the several conditions just mentioned in any way, as they must be quite familiar to anyone who has been properly trained in physical examination of the chest. There are two or three practical points, however, to which I desire to refer.

(*a*) I think that there is a very prevalent tendency to expect pronounced signs of consolidation in the early period or so-called "first stage" of phthisis and hence to fail to recognise the presence of the disease until it has made considerable progress. As a matter of fact it is often some time before the signs of pulmonary consolidation are at all characteristic, except, of course, in cases of an acute or subacute type with definite pneumonic lesions.

(*b*) In cases where the signs are practically of the nature of adventitious sounds or râles, heard on auscultation, there is much danger of regarding them as merely bronchitic, when they really indicate a grave type of tuberculous phthisis. Moreover, when bronchitis, especially with much emphysema, has previously existed as a chronic condition the supervention of phthisical lesions may be very difficult to detect and needs to be watched for with particular care. It may be affirmed as a general statement that adventitious sounds limited to the upper part of the chest, and especially to one side, even though there be no definite signs of consolidation, are not merely bronchitic and should always be regarded with suspicion and as usually indicating a phthisical process.

(*c*) Another mistake which I have found very prevalent is to expect the typical signs of a cavity or cavities in the lung before coming to a diagnosis that such a lesion exists. It not uncommonly happens that a vomica is so small that it gives no characteristic signs whatever and we have to rely simply on the character of the râles, commonly described by the comprehensive but somewhat indefinite term "crepitation," and especially *those brought out with or after the act of coughing*. Of course, it is difficult in certain cases to distinguish between mere softening and small cavities but I feel sure that the latter are not uncommonly overlooked when they ought to be recognised, and I have known cases where the lungs have become riddled throughout with cavities which were never diagnosed for the reason to which I have just referred. On the other hand, it must be noted that sometimes the signs of cavity are simulated when such a condition does not exist. When a cavity or cavities are present the signs should always be carefully studied in order to determine as accurately as possible the actual conditions with which we have to deal in relation to these lesions.

(*d*) I have been much struck by the fact how frequently the existence of pronounced fibrosis in cases of thoracic phthisis has been misunderstood, as distinguished from the primary consolidation, especially when limited to an apex. Many a time have I known such a condition diagnosed as the "first stage" of consumption when in reality it was the "fourth stage," if such terms should be applied to the pathological changes at all. The pronounced differences between the signs of early consolidation and those of late induration ought therefore always to be kept prominently in mind in order to avoid serious error.

(*e*) There is one factor which must not be overlooked in the class of cases known as "mechanical phthisis," as contributing to signs of consolidation, and that is the presence in the lungs of solid particles inhaled from without, which may ultimately form considerable and widely-diffused accumulations.

7. It is well to make it a rule in cases of thoracic phthisis always to examine the *heart* and in doing so not to forget the *pericardium*. The *great vessels* also should not be overlooked, especially in patients at or beyond middle life. The cardiac action may be important in itself, apart from the organic changes which have been already referred to. When the heart is extensively exposed the signs are so remarkable as to lead to the erroneous diagnosis of serious cardiac disease or aneurysm, if they are not properly understood. It may be noted that unusual conduction or abnormal quality of the heart-sounds may help in the diagnosis of changes in the lungs in cases of phthisis, or the cardiac action may bring out certain signs in connexion with cavities. Should an aneurysm be present it must receive special attention. A murmur over the subclavian artery, especially on the left side, is not uncommon in cases of chronic phthisis, due to pressure by thickened pleura; and sometimes a loud systolic bruit, or even a thrill, can be detected over the pulmonary artery or possibly over the aorta.

8. It will suffice to note that physical examination may reveal *glandular* or other *mediastinal* changes in cases of thoracic phthisis, and the structures occupying this region must not be overlooked. Moreover, owing to marked contraction of the lungs in very chronic cases, usually accompanied by firm adhesions to the diaphragm and to changes in this structure itself, the adjacent abdominal organs—stomach, liver, and spleen—not uncommonly are drawn up beneath the ribs to an abnormal height, and thus give rise to signs which are liable to cause confusion unless their cause is recognised.

If the course of procedure which I have thus endeavoured to sketch with regard to the application of physical examination of the chest in relation to thoracic phthisis is systematically carried out I venture to affirm that in the large majority of cases the conditions present can be determined without much difficulty, perhaps not in every detail but with sufficient accuracy for practical purposes. Sometimes, however, especially in very chronic cases, they are so extensive and complicated that they can only be made out by very thorough and careful investigation by an experienced observer, and even then it may only be possible to arrive at a proximate diagnosis as to the actual conditions which involve the thorax and its contents.

3.—*Special Instruments and Apparatus.*

To this point I shall refer only very briefly. I can well remember the time when much importance was attached by some authorities on phthisis to the employment of various instruments, to determine more accurately details as to the size and shape of the chest and the movements of respiration, and also of the spirometer. So far as I can judge these supposed "aids to diagnosis" have practically fallen into disuse and in my opinion rightly. Ordinary measurements or the cyrtometer may be of service under certain circumstances, but elaborate apparatus of any kind is, according to my experience, quite uncalled for and cannot be relied upon to afford any really useful information for diagnostic purposes in cases of thoracic phthisis.

4.—*Examination of the Sputum.*

The examination of the expectoration on scientific lines in cases of actual or suspected phthisis has taken such a firm hold upon the profession generally, and is now so familiar in all its details, that I almost feel as if I ought to apologise for doing more than giving the subject a passing notice in these lectures, especially as I can only deal with it very superficially. Still, there are certain practical points which cannot be passed over altogether in silence. At the outset it must be insisted upon that no practitioner who has any regard for his professional and scientific reputation, or who desires honestly to avail himself of every means of diagnosis at his command, can nowadays safely ignore or omit the systematic examination of the sputum in cases of this nature If he is not competent to do so himself or has not the time or opportunity, there are scientific laboratories, public and private, where everything that is necessary can be done for him, and, indeed, the more advanced methods of investigation can only be properly carried out by a bacteriological expert. It must be further noted that the examination has often to be repeated again and again at varying intervals.

I have already referred to expectoration as a mere symptom, but I must here again insist upon the great help to be derived from a careful general observation of the materials thus discharged, as regards their amount and characters, as indicating the actual morbid conditions and processes which are associated with the respiratory structures. It is necessary, however, to guard against attaching too much importance to so-called "nummular" sputum or other particular varieties supposed to be characteristic of "cavities" in the lungs Calcareous particles or masses may be present, to which patients attach much more importance than they deserve.

I think it may be affirmed that chemical examination of sputum is practically of little or no value in cases of thoracic phthisis. Microscopic examination in a general way, aided by staining in some instances, is useful in revealing blood-corpuscles or minute clots, fibrinous casts, pus corpuscles, various organisms—pneumococci, streptococci, staphylococci, aspergillus, &c.; and elastic tissue. The last-mentioned structure is demonstrated by a particular procedure which I need not describe and is of course important as indicating destructive changes in the lung, while it differs in its exact characters according as it comes from the bronchi, the alveoli, or the arterial walls. It is, however, to the investigation for *tubercle bacilli*, as must be familiar to you all, that examination of sputum is nowadays specially directed, and on this matter I desire to offer a few practical comments In an ordinary way it is only necessary to look for these organisms under the microscope, with their characteristic staining, but under certain circumstances cultures have to be prepared or their presence in expectoration can only be determined by the results of inoculation of animals. Details as to these matters are quite beyond my purpose

The positive demonstration of the presence of tubercle bacilli in sputum is obviously of the greatest value in diagnosis and is generally regarded as an infallible evidence of the existence of tuberculosis, while their number gives some indication as to the activity of the disease, especially at an early period. There can be no doubt that in a certain proportion of cases the positive diagnosis of phthisis can be thus made before physical signs are at all definite or characteristic; and in suspicious cases, particularly when chest symptoms are persistent, it is well to make it a rule to look carefully again and again for tubercle bacilli in any materials that may be discharged, including blood should hæmoptysis occur.

But there is an opposite side to the question. I feel sure that there is an impression abroad in the profession, as well as amongst the laity, that no positive diagnosis of phthisis can be made unless, and until, tubercle bacilli are detected in the sputum or their presence is proved in other ways. Now, it is an undoubted fact that for a considerable time, even in well-marked cases of phthisis, and, indeed, sometimes throughout there may be no expectoration whatever to examine, and I object strongly to the practice of making patients force something from the throat, naso-pharynx, or even the nasal cavities, in order to find tubercle bacilli which are not present, as I have known happen more than once. Moreover, when other symptoms and physical signs of thoracic phthisis are evident enough I do not see why we should wait to examine the expectoration, when it comes, before making a definite diagnosis And still further, it is a well-known fact that in undoubted phthisical sputum tubercle bacilli may be very difficult to detect and repeated examination by a bacteriological expert may be required before they can be positively demonstrated Moeller has recently advocated a remarkable course of procedure in relation both to the patient and the sputum in order to detect tubercle bacilli in suspected cases when they are not revealed in an ordinary way, but it seems to me that this is rather needlessly stretching the point. Another aspect of the matter is that in advanced cases of phthisis, with abundant pus-formation in cavities, tubercle bacilli may practically disappear, while *pyogenic cocci and other* organisms take their place. Expectoration may also become very slight or even cease when the lungs become fibrotic, and here, again, investigation for tubercle bacilli becomes of no value. I mention this point more particularly because I have known cases in which an arrested phthisis, with former cavity and dense fibrosis, was mistaken for "early consolidation" and the organisms were sought for again and again in the small amount of sputum that could be obtained in order to confirm the diagnosis, but without any result. And, lastly, it must be noted that tubercle bacilli can tell us nothing whatever about the various conditions met with in chronic cases of phthisis which I described in the preceding lecture.

The detection of tubercle bacilli in the expectoration in *acute* chest cases, the nature of which is doubtful, is of considerable importance and they may be present in great numbers. Care must, however, be exercised under such circumstances against giving a too positive unfavourable prognosis because these organisms swarm in the sputum, as I have learnt more than once from personal mistakes.

It is important to note that the inability to discover tubercle bacilli after repeated and efficient examination may be of decided negative value in diagnosis when chest symptoms are present, accompanied, it may be, with more or less general symptoms, as well as with physical signs pointing to some pulmonary mischief, particularly at an apex.

5.—*Examination of the Throat and the Main Air-passage.*

In all cases of definite thoracic phthisis it is desirable to inspect the throat, as morbid conditions in this region often aggravate cough and may be important from other points of view. Actual tuberculous lesions are very rare here in my experience, but they may be present, as well as on the tongue, causing much pain. Of course, examination with the *laryngoscope* is often called for, but it is not necessary or desirable to put the patient to the discomfort or distress of such an examination unless it is really indicated. It is not only useful for the recognition and study of tuberculous lesions affecting the larynx but also sometimes to observe similar lesions in the trachea. Further, laryngoscopy is valuable from a negative point of view as showing the absence of tuberculosis and that symptoms are merely due to catarrh or other less important conditions, or that there is only "accidental" motor disorder of the laryngeal muscles. In certain cases it may be desirable to employ rhinoscopy as well.

6.—*Removal of Fluid or other Morbid Products from the Chest.*

Apart from treatment it may be desirable to obtain fluid from the pleural cavity in cases of definite thoracic phthisis or in those of suspected tuberculous pleurisy. Its general nature and characters must be noted; and afterwards it may be investigated chemically, microscopically, and bacteriologically, according to circumstances. A tuberculous sero-fibrinous effusion or empyema is usually sterile or contains very few bacilli but in some instances they are definite enough Cultures may be obtained or the inoculation test applied as a means of diagnosis. Possibly other products, besides fluid, might be taken away from the thorax under particular circumstances for bacteriological investigation For the practical application of these methods the aid of a skilled bacteriologist is required.

7—*Inoculation of Tuberculin: Reaction-test.*

The inoculation of tuberculin, in order to bring out the reaction-test of Koch, with which I take it for granted you are acquainted, may be employed with advantage as an aid in diagnosis of tuberculous disease in the chest in difficult or obscure cases. At the British Congress on Tuberculosis Koch spoke strongly in favour of this method and it has been found useful by other observers, though it has not found much favour in this country as applied to the human subject, and personally I have never had occasion to employ it. I understand that it is now practised as a matter of routine in Osler's wards at the Johns Hopkins Hospital in Baltimore.

8.—*Agglutination-test.*

Certain observers have maintained that the serum of tuberculous patients will agglutinate the tubercle bacilli, on the same principle as in Widal's test for enteric fever but to a less degree. More recent researches have, however, not given satisfactory results, and have shown that the reaction is very inconstant and not specific and therefore cannot be relied upon in the diagnosis of doubtful thoracic tuberculosis.

9.—*Roentgen Rays—Skiagraphy.*

The Roentgen rays have been applied to the investigation of thoracic phthisis, more particularly with the view of its early detection but also for the determination of the exact conditions present. Personally I have no experience of the use of this method, which can only be carried out on a limited scale at present at any rate, and I must refer you to the writings of specialists in this department. There is a very interesting communication on the subject in the *Practitioner* for July, 1901, by Dr. E. Clifford Beale and Dr. Hugh Walsham.

C.—COURSE AND TERMINATIONS.

Cases of thoracic phthisis present great varieties as regards their mode of progress, duration, and actual termination, but there are certain facts relating to this aspect of the clinical history of the complaint which have an important bearing on prognosis and treatment, though I do not think that they are adequately realised. Time forbids me to discuss them at any length on the present occasion and I must content myself with submitting the following general propositions.

1. The natural tendency of phthisical mischief involving the lung, especially if definitely tuberculous, is to be progressive and even an early and limited lesion gives cause for anxiety with regard to the future.

2. There is no foundation whatever for the supposed "three stages" of the complaint, from a clinical point of view, corresponding to the pathological stages of consolidation, softening, and cavity. This is a popular error which the profession should do its utmost to suppress.

3. In not a few cases the progress of thoracic phthisis is very insidious, without any prominent local symptoms, and this may happen even in acute and rapid cases as well as in those of a chronic type.

4. It is very remarkable how in certain *acute* cases of pulmonary phthisis, if not too advanced, arrest of the disease takes place, sometimes ending in a practical cure, especially if the patient can be placed under favourable conditions. In other instances, after rapid progress, it settles down into a chronic and limited form of phthisis. *Acute pleuritic* cases of definitely tuberculous nature are, as a rule, very unsatisfactory in their progress but some striking exceptions are met with.

5. While recognising the tendency of phthisical lesions to advance progressively we must always be fully alive to the wonderful efforts of nature to oppose and withstand them, to check their progress, and to repair the damage which they have caused, even when the morbid changes are definite, extensive, and of a destructive nature. The more chronic the case is, the more likely are these results to happen. At the same time unaffected portions of pulmonary tissue may become developed and utilised for respiratory purposes, a development which it should be our business to encourage and to help.

6. It is quite extraordinary sometimes to note the combinations of chronic conditions affecting the chest with which patients may not only live but even get on fairly comfortably, especially when their circumstances and surroundings are satisfactory and they are prepared to exercise moderate care. As to cavities, which are generally regarded with such terror, there are thousands upon thousands of persons who go about with these lesions, many of whom do excellent work, public as well as private, and you must all be familiar with such cases.

7. Phthisical cases are always liable to variations in their progress, improvement or even apparent arrest of the disease taking place, followed by exacerbation and further activity. A considerable number of cases of "winter cough" are really of a phthisical nature. However quiescent a case may be, or even after a practical cure, the mischief, unfortunately, is liable to start afresh, it may be after a long interval; and this is not an uncommon experience after a supposed "cure" by the open-air treatment. Accidental complications, sudden or acute, not uncommonly interrupt the course of events, being either serious for the time but ultimately recovered from, or leading to an unexpected fatal termination very speedily or within a short period.

8. We must always be prepared for striking changes in the clinical aspect and phenomena of cases of thoracic phthisis during their progress, not only local, but also in relation to the various remote complications which may supervene. Hence a case often entirely alters in its features before the end comes. The final scene varies considerably in its characters and may be very distressing; but in many instances the end is calm and peaceful, while the patient is, as is well known, generally buoyed up with hope even to the last. Sudden syncope is sometimes the immediate cause of death. Acute mania may supervene towards the close of life in chronic phthisis.

9. Another important point to be borne in mind is that sometimes a phthisical patient lingers on indefinitely when apparently almost moribund, especially when kept alive by devoted nursing and care. And further, an individual in advanced consumption who appears to be rapidly approaching the end occasionally rallies and picks up in a wonderful way, living for a long time afterwards and it may be improving considerably. I remember several cases of this kind brought to the Brompton Hospital, their friends thinking that they had relieved themselves of all further responsibility, but the patients were afterwards returned on their hands vastly improved, sometimes much to their disappointment.

CONCLUDING REMARKS.

I need scarcely say, Mr. President, that I regard it as a very high honour to have been invited to deliver the Lumleian Lectures at this College and I desire to express my sincere acknowledgments that I have been thought worthy of standing in the position which has been occupied by so many distinguished predecessors. The task, however, has been a responsible one and by no means easy of accomplishment. I feel but too conscious of the imperfect manner in which I have performed it, but I trust that the subject which I have attempted to deal with is at least worthy of the occasion. It seems to me that the members of the medical profession, collectively as well as individually, have at the present day a specially grave responsibility in relation to consumption. Undoubtedly there are some aspects of modern teaching and practice which are unsatisfactory, to say the least, while others are distinctly disquieting. It is our manifest duty to look at the whole subject comprehensively and on a broad basis; to deal with our patients on rational and common-sense principles; to educate and guide the laity on right lines; to do our utmost to help in the so-called "campaign" or "war" against this terrible scourge; and to promote all measures, whether private or public, which really make for its prevention or eradication. But I think we ought to be particularly cautious and circumspect as to what we say and what promises and predictions we declare about the future of phthisis in general, as affecting communities, as well as in relation to individual cases. The "optimistic platitudes" which are now so widely and dogmatically expressed and written are, in my opinion, doing serious mischief in various ways. On the other hand, it is most important that every individual practitioner should recognise the practical advances which have been made in the treatment of this disease, and he cannot be too cautious as to what prognosis he gives of an unfavourable kind. There can be no doubt that very rash opinions are not uncommonly expressed as to the inevitably fatal termination of a particular case of thoracic phthisis within a short time, especially if it happens to be acute and active, which is then "given up," and the patient falls into the hands of some quack who, if improvement does take place, naturally gets the credit of having saved a "hopeless" case of consumption, which he is not slow to advertise by every possible channel. And I would further utter a word of warning against giving anything like a definite opinion as to the duration of a case of phthisis. No reliance can be placed on the general statistics collected by different writers on this point and every case must be thoughtfully studied on its own merits. Even then it is often quite impossible to give a safe forecast as to when the end will come.

While deprecating any extravagant ideas as to the ultimate extermination of thoracic phthisis there can be no doubt whatever as to the great diminution in the mortality from this cause which has taken place during recent years. I have been favoured with the opportunity of submitting to your notice some remarkable statistics bearing on this point, the outcome of personal investigation by Dr. John F. W. Tatham. These have not yet been published, but Dr.

Tatham has most kindly forwarded them to me with permission on his authority to make any use of them I please.

Mortality from Phthisis in England and Wales per 1,000,000 Living

Age groups	Males		Females.		Reduction per cent. in 1896-1900	
	1861-70.	1896 to 1900	1861-70	1896 to 1900.	Males	Females
All ages	2467	1527	2483	1129	38·1	54·5
Under 5 years	990	390	947	325	60·6	65·7
5 to 10 ,,	431	138	477	199	68·0	58·3
10 to 15 ,,	605	192	1045	408	68 3	60·9
15 to 20 ,,	2190	698	3112	1137	69·0	63·5
20 to 25	3883	1849	3967	1522	52·4	61·6
25 to 35	4094	2338	4378	1843	42·9	57·9
35 to 45 ,,	4166	3135	3900	2084	24 7	46·6
45 to 55 ,,	3881	3220	2850	1589	16·8	44 2
55 to 65 ,,	3297	2681	2085	1231	18·7	40·4
65 to 75	2024	1633	1239	794	24 3	35·9
Above 75 years	659	657	447	366	15·5	18 1

The above table speaks for itself and is a strong encouragement to the profession generally not to relax in the least degree the efforts that are being made to reduce still further the mortality from phthisis, to cure it in its earlier developments, to prolong the lives of those who are victims of the disease, and at the same time to mitigate their sufferings so far as circumstances permit. I submit, finally, that these objects can only be attained by the intelligent study of thoracic phthisis on a comprehensive basis, and the rational employment and application of preventive and remedial measures and agents founded thereon

The Hunterian Oration

ON

ORGANO-THERAPY.

Delivered before the Hunterian Society on Feb 12th 1902,

BY ARTHUR T DAVIES, M.D CANTAB,
F R C P LOND,

PHYSICIAN TO THE ROYAL HOSPITAL FOR DISEASES OF THE CHEST AND TO THE METROPOLITAN HOSPITAL; PHYSICIAN (IN LONDON) TO THE ROYAL NATIONAL HOSPITAL FOR CONSUMPTION VENTNOR.

MR. PRESIDENT AND GENTLEMEN,—No one who undertakes the task of delivering the annual oration before this venerable society can do so without feeling the honour which it implies and the responsibility which it carries. I am deeply sensible of the former and am only too conscious of the latter

[Dr Davies after a few introductory remarks, proceeded to recall to his hearers how intimately acquainted John Hunter was with the profound influence of the essential generative organs upon the animal economy and mentioned that the primitive use of animal extracts seemed to have been that they were given with a view to influence sexual functions He gave references to, and extracts from, various authors dealing with the use of animal substances in medicine from the Ebers Papyrus B.C. 1500 down to the latest instances revealed in the recently published Blue-book about the concentration camps.[1] He then said]

Dr William Salmon in his work, "The New London Dispensatory," published in 1677, which is a kind of extra Pharmacopœia, gives an enormous number of preparations of extracts from the human body and from all kinds of animals Thus there is a preparation of the cor hominis in powder for epilepsy, also of the ox, the stag and the pig, the horn of the stag, the rhinoceros, and the unicorn, the liver of the wolf, the otter, and the frog, and the marrow of the goat, the ox, the stag, and the calf There are several preparations from a man's skull—thus there are the tinctura, the aqua oleum sal, and the essentia cranii humani, also a spiritus cerebri humani—and a number of preparations from the mummy, as well as definite directions for making artificial mummies He considers the body of a healthy young man as the best for the purpose We have an interesting reference to the use of the spiritus cranii humani in the case of King Charles II. The symptoms of his case and the medical treatment adopted by the 14 physicians have been well narrated by Sir Henry Halford[2] and Lord Macaulay[3] The latter, after describing the king's urbanity with which he apologises for the unconscionable slowness of his death, says "The patient was largely bled, a hot iron applied to his head, a loathsome salt extracted from human skulls was forced into his mouth" Macaulay adds "The 14 doctors who deliberated on the king's case contradicted each other and themselves Some of them thought the fit was epileptic and that he should have his doze out. The majority pronounced him to be apoplectic and tortured him during some hours like an Indian at the stake. Nothing better than dissension and vacillation could be expected from such a multitude of advisers. But many of the vulgar not unnaturally concluded, from the perplexity of the great masters of the healing art, that the malady had some extraordinary origin—i.e, murder' Sir Henry Halford states that the salt was given in a julep of 25 drops "ad refocillandas regis vires." He also states that he saw a prescription for the same preparation which was found in the house of Cromwell's apothecary in Duke-street, Westminster, and which was used in the case of Sir Nicholas Throgmorton

[Coming to the modern uses of organo-therapy Dr Davies proceeded]

TESTICULAR EXTRACT

The scientific use, and consequent revival of animal extracts as therapeutic agents in modern medicine may be traced to the lectures given in 1869 at the Paris School of Medicine by Dr Brown-Séquard, his principal object being to establish the fact that all glands with or without excretory ducts give to the blood by an internal secretion principles which are of great importance, if not necessary, and his experiments, made at Nahant, Boston U S A., in 1875, confirmed this view and he further thought that if the internal secretion of a gland taken from a living animal could be safely introduced into the blood of men suffering from lack of that secretion important therapeutic results would follow In 1889 he read a paper before the Biological Society of Paris in which he stated that he had found the means and that it consisted of subcutaneously injecting the liquid extract obtained from glands under pressure He first injected himself with the fresh extract of the testes of young dogs with the result that he experienced a return of vital energy and rejuvenescence with renewed and efficient peristalsis and control over the bladder and sphincter From these results he started the theory that the testes secreted into the blood certain products which powerfully influenced the bodily metabolism, more especially that of the nervous tissue. Pasteur, Bogroff, Variot, and many others confirmed his view, while others have entirely failed to obtain any result at all, in some cases it may be due to the fact that the glandular extract was not given fresh, as directed by Brown-Séquard, as sometimes it was boiled or dried or given by the mouth. Brown Séquard and D Arsonval have stated that, unlike the thyroid thymus or medulla of bones the sexual glands and the pancreas are inert if swallowed; they recommend either a subcutaneous injection or a rectal one, which is nearly as efficacious. They published in 1893[4] a remarkable series of 342 cases of locomotor ataxy which were either greatly ameliorated or cured. Depoux, Gilbert Victoroff of Moscow, and Ouspensky report 85 per cent. of successes in various scleroses of the spinal cord and 90 per cent. in locomotor ataxy. In 103 cases of cancer 97 were ameliorated, as shown by the healing of ulcers and cessation of pain and hæmorrhage, but the tumours themselves were unaffected. In phthisis Cornil, Hénocque, Lemoine and Variot, and others obtained favourable results, also Constantin Paul. Although Brown-Séquard's results have not been confirmed by subsequent experience, yet his general statement as to the restorative power of testicular juice when subcutaneously injected is practically admitted. It produces a steady increase of oxyhæmoglobin, cardiac force is strengthened, vascular tone is exalted, and oxygenation of waste products is promoted (as indicated by the increase in urea) and diminution of phosphoric acid in the urine. The mind becomes more clear and active. In anæmia the hæmoglobin has increased from 3 to 14 per cent. and in tuberculosis it has caused the cough to lessen with general bodily improvement and fall of temperature. In insanity its effects have been indefinite, except in some cases to improve the physical condition. Although the internal secretion of the gland has not been actually obtained the results of castration in children point to its existence, for it is well known that in such cases the hair does not grow, the skin remains soft, the arm and leg lengthen and the muscular state is poorly developed, the voice remains a treble, the mammæ undergo enlargement, and such persons in later life tend to grow fat. Grey Edwards[5] has published six cases in which much benefit was received by taking tabloids of orchitic extract. A. E. Wright[6] of Netley recommends the testicle minced up and locally applied for arresting surface hæmorrhage on account of the nucleo-albumin which it supplies.

OVARIAN EXTRACT.

It is stated by Brown-Séquard that ovarian extract has a similar but less powerful effect than testicular extract and he quotes 63 cases of old women benefited by its use. That the ovary contains some secretion of powerful physiological influence over metabolism is seen in cases of young girls whose ovaries have been both removed—a practice apparently common in barbarous parts of Asia. In such cases the characteristic changes at puberty do not occur, the pelvis does not enlarge, menstruation is absent, and the mammary glands and genital organs atrophy; further, certain abnormal changes peculiar to the male occur, as pointed out by Hunter, such as growth of hair in the form of a beard or moustache; and the voice is more masculine than usual. Similar changes occur in a modified degree after double ovariotomy in adults, in whom this operation tends also to cause melancholia, palpitation, giddiness, and obesity. These symptoms are often relieved by the therapeutic administration of the ovarian extract which also often benefits such conditions occurring in the normal menopause. Cattle-breeders are well aware that removal of the ovaries in the cow increases the richness of the milk and also its quantity. That this condition occurs when all connexion with the spinal cord or sympathetic is severed points strongly to some internal secretion from the ovary into the blood influencing the mammary gland which favours metabolism. In favour of this it has been proved that double ovariotomy causes diminution of metabolism with increase of bodily fat and a lessened excretion of phosphoric acid. Bescon and Camboulois ("Le Suc Ovarien, Effets Thérapeutiques") have found great benefit in the use of ovarian extract after castration and in amenorrhœa with chlorosis and in the menopause.[7] Professor Landau used extract of pig's ovaries with beneficial results in climacteric troubles and in the symptoms following oöphorectomy and amenorrhœa from prolonged lactation and hysteria.[8] Bodon in a case of epilepsy developing at the menstrual period with scanty flow found ovarian extract of great benefit causing cessation of the fits and increased flow.[9] Ferré and Bestron state that ovarian juice can cause death in overdoses and that males are more susceptible than are females. Given to dogs in overdoses the ovarian extract causes erection and ejaculation of semen; in large doses it causes hæmorrhage into the spinal cord and death; it is also given as an aphrodisiac. Stanley Boyd, assuming from Beatson's work the influence of the ovarian secretion over the mammary glands, has performed oöphorectomy in 54 cases of cancer of the breast—19, or 35 per cent., were more or less benefited and 34 were not benefited, or only doubtfully. In Group 1 of successful cases life was prolonged on the average for six months and in 6 per cent. immunity was obtained for two and a half years. It is true that in some of the cases the thyroid extract was given, but it is difficult, as Stanley Boyd states, to estimate its value, for it was only administered when he had satisfied himself that oöphorectomy had failed; he seems to think that the drug has no real effect. Lastly, he points out that Beatson introduced this operation for *inoperable* cases of cancer. Butlin[10] considers the operation of oöphorectomy as useless and Roger Williams considers it as horrible.[11]

THE THYROID EXTRACT.

The study of the theories which have from time to time been put forward with regard to the action of this gland in the economy truly illustrates the drastic criticism of Dr. James Ward on scientific theories. In his work on "Naturalism and Agnosticism"[12] he tells us: "The story of progress is briefly this—divergence between theory and fact one part of the way, the wreckage of abandoned fictions the rest." But the experimental work of Schiff, von Esselberg, Kocker, Victor Horsley, Murray, and others has thrown a flood of light on the subject and has established that myxœdema and its infantile form cretinism are diseases caused by the loss of the colloid secretion of the gland due to atrophy of its substance. The clinical results obtained, first by grafting a portion of the gland, as suggested by Horsley, in myxœdema, and, secondly, by injecting subcutaneously a glycerine extract of the gland, according to Murray's method, are truly astonishing. A large number of cases have now been published of the remarkable results obtained.

Since 1889 I have had 17 cases of myxœdema under my notice. Four of the patients were men and 13 were women. I have been able to keep in touch with all the male cases and with nine of the female patients. My earliest case is that of a man who had suffered from myxœdema for 10 years. He came under my care in 1889 and I have shown him before the society on two or three occasions. He has now been under the thyroid treatment, first by injections and then by the dried powdered extract, for 11 years, and when I saw him last week he was in excellent health. In another case the patient has been under treatment for 10 years and he is well. Mr. F. E. Cockell a few days ago kindly gave me an account of a case which I saw with him in 1896. He states that the man is in very fair health and that he takes a thyroid tablet occasionally In the fourth male case also the patient after two years' treatment is well. Of the female cases one patient has been under treatment for 11 years, another for 10 years, and the others range over periods of seven years, six years, two years, and one year and are all keeping free from the disease. Of the remaining four patients one has died and three I have lost sight of.

In cretinism Murray, Byrom Bramwell, and Thomson have published some extraordinary results of thyroid treatment—in one case the patient grew four and three-eighths inches in one year and in another six and a half inches in six months—with marked diminution of the blurring of the features, enlargement of the tongue, and the pendulous abdomen. In a woman, aged 27 years, the growth was four and a half inches in three and a half years and a remarkable development of the mammary glands took place with return of regular and normal menstruation and improvement in the mental condition—the last feature, as Murray points out, is much more marked in patients under 20 years of age and is in proportion to the duration of the disease.

It is remarkable that cretinism, like myxœdema, is more prevalent in the female sex than in the male sex, though not by any means in the same proportion, it being practically two to one against seven to one in the latter. Further, there is an undoubted connexion between goitre and cretinism, as it has been well attested that in districts where both are endemic one generation may be affected with goitre and the succeeding one with cretinism. Besides myxœdema and cretinism Murray[13] has well shown that the simple parenchymatous goitres which occur in adolescents and young adults derive great benefit from thyroid administration, and further that it is often quite sufficient to obviate the necessity for surgical interference. It would seem that in these cases, as he suggests, the gland is called upon for extra secretion, that true hypertrophy is set up, and that the artificial supply enables the gland to rest and to undergo a partial atrophy and so diminish in size Under this treatment the enlarged gland may lessen to two-thirds, one-half, or even one-third of its former size In cases where there are adenomata or cysts this treatment causes diminution of the gland tissue itself in which they are imbedded and thus enables an operation to be carried out more easily Kennicut[14] collected 60 cases of non-malignant and non cystic cases of goitre, 14 of which were cured, 29 improved, and 17 not improved. Angerer[15] states that in 79 cases which he treated by thyroid extract the goitre was diminished in all of them Stabel reports improvements in 92 per cent of the cases and that when treatment was discontinued the goitre began to increase.

Besides the thyroid tissue itself there are four bodies in close anatomical relationship with it termed the "parathyroids" and it has been shown experimentally that when portions of the thyroid body are removed a compensatory hypertrophy takes place but that the structure thus produced is normal parathyroid tissue rather than normal thyroid Again, the structure of the thyroid body in exophthalmic goitre resembles more closely that of parathyroid tissue than *normal thyroid; and, lastly, experiment demonstrates another* remarkable fact, as yet unexplained, that removal of all the parathyroid bodies, small as they are, is followed by the same fatal effect that follows complete removal of all thyroidal tissue, and although the parathyroids do not contain colloid material yet Hutchison has found iodine in their composition. The removal of the parathyroids, according to Gleg, causes tremor, slow and unstable gait, and emaciation—a very different condition to the effects caused by removal of the thyroid itself, which, as Murray has shown, produces in the monkey subcutaneous swelling, dryness of skin, loss of hair, and a subnormal temperature. It is certainly remarkable that though the parathyroids contain iodine they have no effect when given in myxœdema and that in exophthalmic goitre, the symptoms of which partially resemble the loss of the parathyroid, they are in no way beneficial. From the symptoms of thyroidism and the clinical contrast of the two diseases it has been supposed that exophthalmic goitre is due to over-action of the thyroid gland and the administration of the thyroid extract, which was recommended at first, has not been considered advisable, indeed, in many cases it produces positive harm.

Tempting as the theory is that exophthalmic goitre can be explained on the "over action" theory, yet, as Hutchison points out, the absence of uniformity in the histological changes of the gland, the fact that the symptoms may be unilateral, and that the gland itself may not in some cases be enlarged in Graves's disease and can hardly be considered as over-acting, and the absence of any toxicity or alteration in the colloid secretion of the enlarged gland tends to destroy this hypothesis.

The thyroid extract has been used by Beadles,[16] Carter,[17] Claye Shaw,[18] and Woods,[19] and found useful in cases of myxœdema with insanity, and the latter condition has in some cases been entirely cured. Macpherson[20] and Dunlop, Bruce and Macphail extended the treatment to insanities generally—and these results met with so much success that many others have used the thyroid but with very varying results, *the recoveries being from 0 to 50 per cent.* Out of 1032 cases collected by Mabon and Babcock[21] 16 8 per cent. of the patients recovered, 24 per cent improved, and 59·2 remained unimproved Easterbrook treated 130 cases and had 12 per cent. recoveries, in cases which were intractable to other forms of treatment. Large doses were used in every case except in the myxœdematous form, and Easterbrook seems to think that it is the briskness and intensity of the metabolic reaction produced which is the valuable effect in large doses in insanity, and that the drug clears out of the system various transitional, and perhaps toxic, products of metabolism. All the patients who recovered improved physically as well as mentally He concludes by saying that the thyroid is a powerful metabolic stimulant and that the early quickening of the pulse, the phosphaturia, and nervous and mental symptoms, all point to a special affinity of the drug for the nerve centres, further, that while small doses were tolerated well by the patients in all of his cases large doses were badly borne by those under 20 years of age, and much more so by those over the age of 60 years, the former specially tending to lose weight and the latter to exhibit failure of the pulse, also by patients who were emaciated and those also who were obese, probably in the latter case due to fatty degeneration of the heart. In cases of valvular heart disease the drug was borne well, but these patients were also treated by rest and cardiac tonics Four of his patients had carcinoma of the lower lip, œsophagus, pylorus, and pancreas respectively No amelioration was produced except in the pyloric case, in which the gastric symptoms disappeared, the patient increased in weight and had a continuance of good health for two years when fatal hæmorrhage occurred, the diagnosis was confirmed post-mortem. The parathyroid extract has no effect in insanity except to raise pulse tension (Easterbrook The Medico-Psychological Association Prize Essay, p 38)

The therapeutic use of the thyroid extract has been *extended in many directions, to which* I will refer, although time does not permit me to do so as fully as I could wish. Byrom Bramwell,[22] struck by the marked changes in the condition of the hair and skin after thyroid treatment in myxœdema, determined to try its effect in certain skin affections and obtained some remarkable results in psoriasis, lupus, ichthyosis, and alopecia. In a paper read by myself before this society[23] *on Oct. 25th, 1894, I narrated cases of* psoriasis, ichthyosis, and chronic eczema which I had treated with much benefit in this way Abraham has published the results in 90 cases of different skin affections and has shown that there is a minority benefited by thyroid extract Pringle[24] has shown from a careful and systematic study that the thyroid produced the more easy formation of healthy cicatrix in cases of cutaneous tubercle properly and systematically treated and thus tends to prevent badly-developed and unhealthy scar tissue. The type of case which answers best is that with superficial ulceration and hyperkeratosis. Sir Hugh Beevor[25] showed before this society in 1898 two remarkable cases of universal alopecia successfully treated by thyroid extract. In tetany the extract has been used with marked benefit and success, which is interesting, as tetanic symptoms have often been observed after thyroidectomy It is also very useful in relieving spasmodic torticollis, also in fibroid of the uterus and uterine hæmorrhage of some kinds it is said to be useful Wooldridge showed some years ago that thyroid juice destroys anthrax poison In certain forms of obesity the thyroid extract has produced remarkable results and it has been found of use in promoting union of fractured bones (Gautier) and in progressive myopathy, according to Lépine, it is beneficial.

In 1896 Beatson of Glasgow introduced the operation of oöphorectomy *combined* with the administration of thyroid extract for cases of inoperable carcinoma of the breast and obtained some striking results and last year he reported another successful case Herman has reported eight cases which he has treated in this manner and which he has subsequently watched. In one the patient was alive and well four years after the operation, in the second and third life was prolonged by about 18 months of good health, in the fourth by one year, in the fifth and sixth no benefit occurred, in the seventh there was some benefit, and in the eighth there was decided benefit. Other surgeons, such as Watson Cheyne, Eve, and Lockwood, have obtained similar results, but Langton has stated that only from 18 to 19 per cent. are benefited by this treatment, and Butlin, who gave thyroid alone in his cases, obtained no benefit from it in any.

A remarkable case is recorded by Mr. F. Page and Dr. W. H. Bishop[26] of a woman, aged 61 years, who was twice operated upon for carcinoma of the breast and its subsequent recurrence. As another recurrence took place a further operation was declined, and the thyroid treatment alone was tried for a period of 10 months, at the end of which time the disease had entirely disappeared, but six months afterwards there was another recurrence and the patient died.

THE SUPRARENAL EXTRACT.

In 1836 Brown-Séquard, struck by Addison's work, investigated the action of the suprarenal glands and published the results of his experiments in animals, which are as follows. 1. That removal of the two capsules in dogs, cats, and rabbits and other animals causes death rapidly and more so even than extirpation of the kidneys. 2. That if a long interval is left between the removal of one and that of the other capsules life may last long, but as shown by Tizzoni the animals die after considerable weakness or paralysis from a special organic disease of the nervous centres. 3. That the blood of animals deprived of the suprarenals is a poison acting powerfully on other animals, as shown by Langlois and Abelous. 4. That animals dying from the absence in blood of the secretion of these glands after removal can be revived at least for a time by the injection of the liquid suprarenal extract. These statements of Brown-Séquard were entirely confirmed by Abelous and Langlois and although the experimental work of other observers, amongst whom Tizzoni's must be considered as important, as pointing in a negative direction, yet all modern work tends to confirm strongly the conclusion that the suprarenals are functional glands of importance to the animal economy. In 1894 Chaufford[27] published an account of a female patient, aged 35 years, suffering from Addison's disease, whom he treated by subcutaneous injection of suprarenal extract prepared according to D'Arsonval's formula—13·5 cubic centimetres being given in the course of nine days; the result was doubtful. Similarly, Bra[28] recorded two cases—a man, aged 37 years, and a woman, aged 42 years —whom he had treated with negative results. Oliver[29] has published an account of a patient who took 45 grains daily of the extract; there was improvement in every respect, the bronzing became less, the appetite improved, and nausea seldom occurred. The case was under observation for two years and improvement was maintained so long as the treatment was kept up. He records, also, two other cases which derived benefit from the treatment and also another under the same treatment for 11 weeks without marked benefit. Box has recorded in the St. Thomas's Hospital Reports[30] the treatment of six cases of Addison's disease by the suprarenal capsule administered either by the mouth or by the rectum, but as four of the patients were in an advanced stage of the disease one cannot draw any conclusion; in two other cases, however, although large doses were given, amounting in all to 7200 grains in one case and 3256 in the other, no real improvement took place in either. Although, as I have stated, Schäfer and Oliver found that the active principle of the suprarenal extract is not destroyed by artificial digestion, Vincent could produce no physiological effects on dogs and rabbits by large doses, and Grünbaum failed to raise his own blood-pressure by taking the suprarenal extract by the mouth. Box states that in five out of seven cases the suprarenals were found to be caseous and he records an interesting fact that in one case, where there was no naked-eye evidence of tubercle, a guinea-pig was successfully inoculated with tuberculosis from it. Delépine had previously recorded a negative result. Rolleston, in his Goulstonian Lectures of 1894, records the case of a woman who had improved under suprarenal treatment. Lloyd Jones[31] also published a case of Addison's disease which derived marked benefit in large doses from the treatment, the patient becoming practically well. Similar cases are recorded by Sansom[32] and Stockton[33] Kennicut has recorded 48 cases of Addison's disease, of which six were reported to be cured, 22 improved, 18 unimproved, and two aggravated by the treatment. Ringer and Phear[34] record a case of a woman, aged 28 years, who temporarily improved for four weeks under 45 grains daily, increased up to a quarter of an ounce daily, but who subsequently died. It is interesting to note that Schäfer and Oliver obtained no results from suprarenals the medulla of which was caseous and the cortex of which was sclerosed, showing that there was no active principle. Dyer found the active principle in the suprarenal vein and considered it a true internal secretion. J. S. Bury[35] treated a case of Addison's disease in a girl, aged 13 years, with suprarenal extract without benefit. Douglas Stanley[36] considered that the suprarenal extract in a case of splenic anæmia produced a marked increase in red blood corpuscles. The benefit was temporary; post-mortem examination revealed sclerosis of the spleen, the pancreas, and the suprarenals.

The use of the suprarenal extract, like that of the thyroid extract, has been extended in other directions besides the one for which it was originally given. Langley[37] states that the extract has a specific stimulating action on nerve-endings and that it produces effects similar to the stimulation of some one or other sympathetic nerve. Oliver and Schäfer[38] have shown that it is one of the most powerful vaso-constrictor and cardiac tonics we possess and that it acts alike on striped and unstriped muscular tissue given either locally or by the mouth, and they consider that it might be of the greatest clinical value in cases of sudden cardiac failure due to shock, or hæmorrhage, or an overdose of anæsthetics, or for promoting uterine contraction, and recommend its very slow injection into a vein or, in extreme cases of cardiac failure, into the heart-wall itself. Gottlieb has shown that in animals poisoned with chloroform or chloral until the pulse has almost ceased the circulation is almost at once restored by injecting the suprarenal extract into a vein. Further, another remarkable property of the extract is the smallness of the active dose. Thus one-tenth of a dried gland produces a maximal effect on the heart and arteries of a 20-pound dog, and it is concluded from this that one-eight-hundredth part of a grain is capable of producing a well-marked physiological effect in an adult man, which is the smallest active dose on record of any drug in the Pharmacopœia, and when compared with the dose of digitalis and ergot required to produce a similar result, when subcutaneously injected, is markedly in contrast. Bates[39] has shown that the intravenous injection differs in effect from that of the hypodermic or from that when the extract is given by the mouth. This action of the gland explains very well the extreme muscular debility and weakness and the low arterial tension in Addison's disease where its influence is absent. Acting on the results he obtained Oliver suggested and also tested the value of the extract where there is loss of vaso-motor tension as in asthenia, anæmia, cyclic albuminuria, and diabetes mellitus, in which last condition, according to Pavy, a vaso-motor paralysis involving chylo-poietic viscera may stand at the foundation of the form of diabetes limited to defective assimilation of carbohydrates, also in exophthalmic goitre, heart disease, and capillary hæmorrhages. In one case of cyclic albuminuria Oliver states that the albumin disappeared and that in another it diminished. My experience in these cases so far is doubtful. In two out of three cases of diabetes mellitus under Bradford, Ringer, and Poore at University College Hospital the glucose was diminished. In a case of exophthalmic goitre the pulse-rate was lessened and the thyroid gland and exophthalmia were reduced. If exophthalmic goitre is due to over-secretion and absorption of the colloid material suprarenal extract ought to be of benefit as it has exactly the opposite effect on the vaso-motor system to the thyroid.

Valentine, Cleghorn, Cunningham, Kennicut, and Borulte have confirmed Oliver and Schäfer's results in the use of the suprarenal extract in heart disease. I have not been able to come to any definite conclusion as yet with regard to its value in these cases. Kenworthy has given the extract in 15 cases of hæmoptysis with good results. This I have tested in several cases with apparent good effects in some, but, as you are fully aware, there is no more *quæstio vexata* in medicine than to determine the *post hoc* and *propter hoc* action of drugs in checking hæmoptysis which often tends of itself to cease spontaneously. Cohen states that suprarenal extract is very useful in asthma associated with vaso-motor ataxia in neurotic subjects. T. D. Lister has informed me of a case of asthma with low pulse tension which derived great benefit from the extract. Douglas has found it of great service in hay fever when applied locally or given internally and Curtis has used sprays of it (half a drachm to one ounce). Floersheim[40] has shown that the suprarenal extract often restores strength and regularity to a feeble and irregular heart and confirms Schäfer and Oliver's statement that it does not cause rapidity of action, because it stimulates the inhibitory centre, but that if the vagus is divided the heart's action becomes more rapid and forcible. Bates[41] sums his conclusions as to its action on the heart as follows. 1. The internal administration does not affect the normal heart and normal blood pressure. 2. An intermittent pulse becomes regular and a weak pulse stronger. 3. It is temporary in action. 4. It is the most powerful cardiac stimulant known. He also states that cases of exophthalmic goitre are markedly benefited by it and that all inflamed tissues such as occur in congestion of the eye, the throat, and the larynx, are most decidedly relieved by its application, either locally or if swallowed, and that by its powerful astringent action it facilitates operations on these parts in congestion of the larynx and tuberculous laryngitis with marked benefit. In intra tympanic surgery Phillips has shown that the extract is of great service from its powerful vaso-constricting action. It is remarkable that the extract appears to have no toxic effect whatever, however frequently used internally or externally. As a local application it relieves pain occurring in cancer of the breast, œsophagus, and tuberculous laryngitis and periodontitis as recorded by E. A. Peters[42] and also its topical use successfully arrested severe epistaxis in a case of hæmophilia.[43] In insanity Easterbrook[44] considers the extract of use in cases of acute maniacal excitement where, as Maurice Craig has pointed out, there is low blood pressure and also because it lessens tissue oxidation.

Thymus Gland Extract

The experiments of Turelli on dogs show that extirpation of the thymus causes loss of strength and appetite, with diminution of red cells and hæmoglobin and increase of white cells. Abelous and Billard[45] state that the thymus in the frog is an indispensable organ, total ablation of it causes weakness, paresis, and paralysis, hæmorrhage, and œdema with death from auto-intoxication. Svehla[46] using a watery extract of thymus from man and animals says that intravenous injection in man, in the pig, and in the cat causes (1) lowering of blood pressure, (2) acceleration of the pulse from its action on the heart, and (3) in large doses restlessness with dyspnœa and death. Reinbach who applied the thymus clinically in Mackinley's clinic, says that it causes diminution in the size of goitre in cases of exophthalmic goitre, but in about 50 per cent. of the cases the goitre was unaffected. Hector Mackenzie[47] tested the action of the thymus in doses varying from several ounces to 10 or 15 grains a day on 20 cases of exophthalmic goitre. His conclusion is that it has no effect on the heart or goitre or exophthalmos, but that it appears to be a remedy of some value as it improves the general condition, and some of the patients were satisfied that it benefited them. On the other hand, 15 cases which he also collected are published by different observers—Tatz and Guérin, Arthur Maude, Parker,[48] Metcalfe,[49] Owen and Cunningham[50]—in 14 of which marked improvement took place in the pulse-rate, exophthalmos, and goitre. Dreschfeld[51] tried the thymus in three cases without benefit. Mobius in his work on Basedow's disease says that several patients improved but not more or sooner than under other modes of treatment. I have seen distinct improvement in two cases and also in two cases of tachycardia. Macalister has reported temporary improvement in pseudo-hypertrophic paralysis.

The Pituitary Extract.

Complete removal of the pituitary body causes lowered temperature, loss of appetite, twitchings, tremor, and death. Howell[52] has shown that intravenous injection of the infundibular part of the pituitary gland causes a rise of blood pressure, but that the hypophysial portion does not. This rise is accompanied by slowing of the pulse which still persists, though to a less extent, after division of the vagi. Schäfer and Swale Vincent[53] confirmed these statements and also found a second substance which produces a well-marked fall of blood pressure like cholin, but its action is not neutralised by atropine. Injection subcutaneously of a decoction of the infundibular part of the hypophysis shows a certain correspondence with the action of the suprarenal extract in causing contraction of the arterioles and augmentation of heart-beat. The conclusion of these observers is that at present our observations appear to indicate that there may be specific active substances in the infundibular part of the pituitary gland which usually do not occur in nervous matter.

The pituitary extract has been used in cases of acromegaly owing to its hypertrophy being considered as a primary cause of disease. Ransom[54] has obtained negative results in two cases with its use. H. D. Rolleston[55] has published a case treated by the combined use of thyroid and pituitary extract on the theory that the gland is sometimes enlarged in myxœdema and is vicarious in action, and though Schäfer and Oliver have shown that the intravenous injection of the infundibular part of the pituitary extract and thyroid are exactly opposite in effect, yet they have found a second body in it which, like the thyroid extract, produces a fall of blood-pressure. In Rolleston's case headache was relieved, but it is well known that this symptom may be relieved alone by the thyroid. A case of acromegaly was shown some time ago by our late President, Mr. F. Gordon Brown, who informs me that the thyroid extract continues to relieve the headache. Probably there is some connexion between acromegaly and exophthalmic goitre, as the former is sometimes associated with some symptoms of the latter, such as pigmentation, and Schäfer and Oliver have shown the similarity in action of the infundibular portion and suprarenal extract on the heart and arterial system. Kennicot has collected 13 cases of acromegaly treated by pituitary extract, seven showed varying degrees of improvement, five none, and one became worse. In two the violent headache and neuralgic pain in the limbs were lessened. R. Caton[56] reported a case of acromegaly which whilst under pituitary extract varied in condition, but showed marked and rapid improvement when the thyroid extract was given alternating with it. Parson[57] also reported a case where the headache was relieved and general improvement took place under thyroid extract. R. W. Dodgson[58] also reports a case of acromegaly in which the lethargy became less and memory improved under the pituitary extract. Von Cyon[59] has shown lately that the pituitary body regulates intracranial blood pressure and bodily metabolism.

Hepatic Extract

At the Thirteenth International Congress held at Paris in 1898 Gilbert and Carnot[60] gave an account of their experimental researches on extract of liver. Injections of the extract in rabbits and dogs, whether subcutaneous or rectal, caused acceleration of biliary secretion and increase in urea and they found that in cases of alimentary glycosuria in man, after absorption of the liver, that the total quantity of glucose eliminated is smaller, the results being more marked when the absorption takes place by the rectum than by the stomach. The liver extract appears, therefore, to stimulate the hepatic cells and to help it to store up more carbohydrates and to transform them better. If there is hepatic over-activity any specific stimulant would tend to still further exaggerate it. In diabetes mellitus due to functional debility of the liver Gilbert and Carnot found the liver extract to be beneficial and they record a case of a woman with diabetic gangrene of the foot in whose case the sugar was reduced from 160 grammes to 38 grammes in four weeks. The patient relapsed several times when the treatment was stopped but each time derived benefit when it was again resumed and the gangrene was healed. In cases of diabetes due to over-activity of the liver the extract does harm by increasing the sugar eliminated; it may be thus used as a means of diagnosis of an under-acting or over-acting liver, as well as a therapeutic agent. In alcoholic cirrhosis with ascites, jaundice, and œdema and hæmorrhages, the extract has proved very beneficial, also in a case of atrophic cirrhosis. According to these authors, pancreatic extract increases the sugar in diabetic cases which hepatic extract controls. I have used hepatic extract in one case of diabetic phthisis and under its influence the sugar apparently diminished. No other medicine was used.

THE PANCREATIC EXTRACT.

Besides the action of the gland in aiding digestive processes it has been found by the experiments of Minkowski, von Mering, and others that it plays an important part in certain forms of diabetes mellitus. By *experimentally removing in toto the gland in dogs they* produced diabetes mellitus; further, Médon showed that if only a small portion of the pancreas be left, even if it has no intestinal connexion, diabetes is not produced, and that even a graft of the gland subcutaneously is sufficient to prevent diabetes. These experiments led Lépine to put forward the internal secretion theory that has been further elaborated by Tuckett who considers that the pancreatic secretion neutralises a toxic substance absorbed from the intestine through the lymph stream.

Although *experimental removal of the pancreas produces* diabetes mellitus it is a remarkable and interesting fact that injections of pancreatic extract, whether subcutaneous, intravenous, or peritoneal, and also pancreatic feeding, have not the slightest effect in preventing the glycosuria and clinically the same has been found to be the case. Dixon and Lépine have published interesting statistics on this treatment.

Hector Mackenzie[61] has published results of two cases treated by the liquor pancreaticus with the result of general improvement, increased strength, and lessened thirst and quantity of urine, but no diminution in the sugar. Neville Wood[62] obtained a similar result possibly due to pancreatic pills but in another case a negative result. Combe[63] has reported a case of diabetes of eight years' duration cured by taking pancreatic sandwiches. He considers that the internal secretion is a glycolytic ferment which renders inert circulating glycoses. Williamson[64] has published an interesting table of 26 cases of diabetes mellitus in all of which the pancreas was examined. In eight well-marked changes were found, in four slight changes, and in five atrophy. He suggests, like Tuckett, that in these cases the glycosuria is due to the absorption of a toxic substance from the intestine which is neutralised by the internal secretion of the pancreas. Lauder Brunton in 1874 tried raw meat for diabetes. Williamson also quotes Gilbert and Carnot[65] who in cases of diabetic extract of definite hepatic origin advise the administration of hepatic extract which they consider acts by either increasing the power of the liver to store up reserves of sugar or to cause a more rapid destruction of hydrocarbons taken as food. In 1868 Langdon-Down[66] published a case of fatty diarrhœa with diabetes which he treated with the pancreatic extract with a very successful result. The fat entirely disappeared from the stools, the sugar also disappeared from the urine, and the man gained in weight. Von Noorden has used pancreas and preparations of it with good result in cases of chronic steatorrhœa accompanying diabetes and in other cases of chronic steatorrhœa depending upon disturbance of the function of the pancreas.

EXTRACT OF INTESTINE.

E. Vidal of Perigueux has shown from experiments on rabbits that if pig's fæcal matter be injected into the marginal vein of the ear the animal developed in 15 seconds violent convulsions and died, whereas in another animal of the weight which had been previously injected with extract intestine and then subsequently injected with fæcal the only symptoms were slight dyspnœa with fairly marked myosis without convulsions and the animal did not die the following evening, from which it would appear that intestinal extract neutralised the toxic effect of the intestinal poison, the subsequent death of the animal being due to the inevitable septicæmia set up by a fluid rich in bacteria. Occlusion of intestine in rabbits, guinea-pigs, and rats showed that where the intestinal extract had been injected immediately the animals lived longer than the check ones and that even where stercoræmia had been allowed to commence injection of the extract preserved the animal's life longer, but in this case a much larger dose was requisite, so that not only has the extract a preventative but also a curative action. Vidal applied this knowledge clinically and has recorded a desperate case strangulated hernia in a man, aged 49 years, with superficial respiration, intermittent pulse, and incessant fæcal vomiting, in whom after injection of the [illegible] intestinal extract the general condition of the patient greatly improved and the removal of an enormous mass of gangrenous tissue, the two ends of the intestine being fixed to the skin, was successfully performed, and after three subsequent injections of the extract the patient recovered without interruption. Vidal concluded that the operation would not have been successful unless the toxic poison had been neutralised. There is no doubt whatever that patients in cases of strangulated hernia, even when the operation has been fully successful, sometimes die from stercoræmic poisoning, and to avoid this surgeons now advise emptying of the bowel above the stricture by a puncture with a small trocar and injecting into the bowel a dose of magnesium sulphate through the cannula after emptying it. Vidal has also recorded a case of invagination in a boy, aged six years in whose case injection of the glycerine extract neutralised stercoræmic poisoning. The importance of this work has been confirmed in quite another direction by alienists.

Since Bouchard's classical work on the toxicity of the urine, when he showed that in normal urine there existed seven toxic substances not present in cases of uræmia owing to retention in the body, great attention has been paid to auto-intoxication from products of the gastro-intestinal canal which are believed to cause certain forms of nerve disease and of insanity. W. Ford Robertson[67] states: "I am strongly inclined to the belief, which is supported by a large amount of evidence, that various forms of toxæmia of gastro-intestinal origin are the chief factors in the pathogenesis of a large array of acute and chronic diseases, including severe mental diseases, such as general paralysis, senile insanity, locomotor ataxy, idiopathic epilepsy, acute and chronic mania, and melancholia," and he has demonstrated in proof of his views marked alteration in the structural condition of the stomach and intestine in general paralysis, leading to auto-intoxication from disordered products of gastro-intestinal formation. Lately John Macpherson,[68] Commissioner of Lunacy in Scotland, has stated in his last report that he regards the symptoms of vaso-motor disturbance and sudden loss of nervous function which are characteristic of the early stages of general paralysis as indicating the probable action of a toxic agent in the alimentary canal, and that it is, in fact, a form of auto-intoxication. Some years ago Sir Andrew Clark started the theory that anæmia and chlorosis in young girls was due to an auto-intoxication from the constipation so commonly associated with this condition. In a minor degree the symptoms of constipation are well known to us all and one is reminded of the saying of Lord Byron in one of his letters where he writes: "Talk of champagne, there is nothing that cheers your spirits like a dose of Epsom salts."

RENAL EXTRACT.

Brown-Séquard, believing that uræmic symptoms are only partly due to accumulation of certain substances in the blood, recommended renal juice in cases of kidney disease and showed from experiments on rabbits and guinea-pigs that life lasted much longer after the extirpation of both kidneys when injections of renal liquid were used, and he points out that there is a marked difference in the mode of death in cases of anuria when the internal secretion continues, even though the kidneys are in great part diseased, to that of cases of disorganisation of the kidney when the internal secretion is stopped, the difference being one of much less violence than in Bright's disease and nephritis In support of his view he quotes the case recorded by Sir James Paget[69] in which for 13 days there was total suppression of urine without any symptoms of any kind He also states that in these cases the condition is not to be explained by vicarious urination of the skin. D'Arsonval injected renal liquid in a case of uræmia with temporary benefit, but the patient ultimately died Neale[70] quoted an analysis and comparison of urine and beef-tea made by Masterman[71] who showed how closely similar they are in composition, the only difference being that beef-tea contains less urea and uric acid, and therefore both are stimulants and not nutritious agents. Neale states that one of the worst cases of epistaxis which he had seen and which had resisted every form of European medicine ceased *after the patient drinking a pint of urine, and he had also* seen in South America a glass of a child's or young girl's urine tossed off with gusto and apparent benefit as a tonic. He states that in that country urine is a common vehicle for medicine and that of little boys is highly recommended for malignant small pox Moss[72] used the glycerinated renal liquid in rabbits, healthy and nephrectomised, and obtained only negative results. In 1852 Bauer found urate of ammonia and guano of great value, if used externally, in phthisis, lupus, and morphœa In 1862 Hastings published an elaborate report on the treatment of phthisis by the excreta of reptiles. Lately H. Harper[73] has given urea in certain cases of phthisis which appear to have derived much benefit from its use—the ground on which it is given being that phthisis and gout are antagonistic

SPLENIC EXTRACT

Schäfer and Oliver have shown that the intravenous injection of splenic extract in a dog causes an immediate fall of arterial pressure, followed by a pronounced continued rise. Wood[74] states that he used extract of spleen with some benefit in exophthalmic goitre but he points out that it is badly borne by the stomach as it causes pain and vomiting and that hypodermic injections are apt to produce local abscess. *He was led to its use in exophthalmic goitre* by the fact of the spleen being enlarged in myxœdema and cretinism and after thyroidectomy, thus suggesting a relationship between the two glands. Carpenter[75] recommends the extract in typhoid fever on the principle that absence of leucocytosis is a marked feature in this disease, and he considers that it ameliorates the symptoms, reduces the temperature, and hastens recovery

In their clinical studies with spleen and thyroid extracts Charles Bois and Neilkerr[76] state that they treated 22 cases with eight recoveries, and they sum up as the result of their investigations (1) that the most general result of this treatment is physical improvement; (2) that its action on the mental state is undoubtedly evident in a fair proportion of cases, especially of adolescents and sometimes direct and at other times owing to improved physical conditions, and (3) that it materially assists in rendering thyroid treatment efficacious, the patient after a course of spleen treatment becoming more susceptible to the action of the thyroid.

PULMONARY EXTRACT

At the French Medical Congress held at Montpellier in 1898 Brunel[77] gave an account of the use of pulmonary juice ("Quelques Indication Nouvelles sur l'Emploi du Suc Pulmonaire") and considered it an effacacious adjuvant in certain conditions where it is possible to stimulate the vital resistance of the patient, but he expressly states that it is not bactericidal or antitoxic in its action ("mais comme un remède renforçant le résistance de l'organisme du poumon en particulier") It acts best in cases of pleuro-pulmonary suppuration with osteo-arthritic condition as described by Marie—in this the amelioration is rapid and the bony deformation is arrested—but it is useless in advanced cases of phthisis. Arnozan[78] has employed pulmonary juice with success in purulent pleurisy of a chronic nature communicating with the exterior either through the pleura or into the bronchial tubes, and non-tuberculous in character and associated with bony changes. He states that the temperature falls, the pus becomes less abundant and more clear, and the articular stiffness and weakness disappear Cassaet[79] ("De l'Action du Suc Pulmonaire") states that tuberculous cases with a chronic pleuro-pulmonary septic condition are much benefited by pulmonary juice.

NERVOUS EXTRACTS.

The researches of Halliburton have shown that extract of sympathetic ganglia produces a fall of blood pressure and that other extracts of the nervous system, as the brain, spinal cord, and ganglia and nerves, produce the same result The effect can be explained on the hypothesis that cholin is the principal active agent. Gumprecht, like Mott and Halliburton, found in normal cerebral spinal fluid minute doses of cholin and in diseased conditions, in which the katabolic side of nervous action is preponderant, cholin is immensely increased. Thus Mott[80] and Halliburton state *that in 150 cases of general paralysis examined by them they* found widespread degeneration, not due to degenerative condition of the nerves but to the production of such powerful poisons as cholin or neurin found in the cerebro-spinal fluid of general paralytics, the poisons being the result of auto-intoxication Brain extract has been recommended by Brown-Séquard and Althaus in epilepsy, locomotor ataxia, chorea, and neurasthenia. In mental diseases no definite results have been produced. Robertson thinks that brain extract may act as a tonic in mild and early cases of neurasthenia.

MAMMARY GLAND EXTRACT

Shober[81] states that extracts of sheep's mammary gland in tablets equivalent to 20 grains of the desiccated gland given by the mouth three times a day have a positive action on the uterus, causing contraction and so diminishing bleeding It is, therefore, similar to ergot but far more reliable and surer, and its continued use has no unpleasant effects in uterine fibroids, characterised by excessive and *weakening menorrhagia* and metrorrhagia, bleeding can be controlled in a few weeks, and the health of the patient is improved The tumours are inhibited in growth and diminish in size up to a certain point, and by its use the patient can be placed in a more favourable condition for operation. It *is also useful in subinvolution of the uterus* from any cause unassociated with cancer or structural change, the uterine canal coming down from three inches to one and half inches in five or six weeks. Leucorrhœa and irregular bleeding cease and backache and other reflexes disappear. It is of no use in cancer, dysmenorrhœa of *ovarian and* tubal origin, or malposition or stenosis

PAROTID GLAND EXTRACT

The extract of this gland is of much use in controlling the pain of uncomplicated ovaritis, where the ovaries are enlarged and prolapsed.[82] Bell of Glasgow has found parotid extract useful in ovarian disorders, especially in cases of enlarged and tender ovaries with dysmenorrhœa, metrorrhagia, chronic *endometritis, and subinvolution.*

I have endeavoured to bring before you a method of therapeutics which, starting from remote antiquity, has come down to the present day, and whilst "tracking out how new thoughts are linked to old ones and seeing how an error cast into the stream of time leaves a streak behind lasting through many changes of the way of man, and noting the struggle through which a truth now rising to the surface, now seemingly lost in the depths, eventually swims triumphant on the flood, we may perhaps the better learn to appraise our present knowledge and the more rightly judge what of the thoughts of to-day is on the direct line of progress"[83] That John Hunter should have independently observed the effects of removal of the essential organs of generation is not surprising—it was simply the outcome of his all grasping and all-observing "don't-think-but-try" intellect. But to him is also due the credit of making there observations in a scientific spirit, and although the words "internal secretion" are not once mentioned in his original paper yet one cannot but feel they are writ large across it. The records of our society show that this spirit of observation has never been wanting in our Fellows. It is only necessary to recall such names as William Blizzard, Clift—who though not belonging to our society attended its meetings—the Babingtons, Richard Bright, John Hilton, and Jonathan Hutchinson to prove our intellectual affiliation with John Hunter. Let us in our turn see that we pass on the sacred fire to those who will come after us, ever mindful of the words of the greatest Hunterian orator "that in the world of thought 'he that is mortal may produce that which is immortal.'"[84]

A CASE OF PURULENT PERITONITIS ASSOCIATED WITH EMPYEMA; RECOVERY.[1]

By HENRY ASHBY, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE MANCHESTER CHILDREN'S HOSPITAL.

INFLAMMATIONS of serous membranes are by no means always confined to one locality; there may be double pleurisy, pleuro-pericarditis, peritonitis, or meningitis associated with pleurisy or pleuro-pneumonia. In these cases the double or treble lesion is due to infection by micro-organisms which have been carried from one organ to another by the blood-stream, or in some cases (as from the left pleura to the pericardium) infection has occurred by direct contact. In "pneumococcal septicæmia," pleuro-pneumonia, peritonitis, and meningitis have been found in the same subject, though in an early stage, as death has resulted from toxæmia before the lesions were far advanced. In other cases the streptococcus or the tubercle bacillus has been the organism which has given rise to the multiple inflammation.

These associated serous inflammations have no doubt a certain analogy to multiple joint inflammations and this circumstance has probably suggested the names of "polyserositis" or "polyorromenitis."[2] It must, however, be obvious that cases of multiple serous inflammations differ widely from one another as regards the infection present and the organs attacked, and nothing but confusion can result from their being included under a common name. The following case is, I think, of interest as illustrating one form of combined serous inflammation—viz., a purulent inflammation occurring simultaneously in the peritoneum and left pleura, fortunately ending in recovery.

The patient was a girl, aged eight and a half years, who was delicate and had suffered a good deal from attacks of bronchitis. She had been fairly well up to Sept. 10th, 1901, when she was seized suddenly with vomiting, diarrhœa, and pain in the abdomen. When seen next day by her medical attendant (Mr. A. W. Senior) the temperature was 103° F., the vomiting was incessant, the stools were foul and liquid, and there were cough and some expectoration of mucus. The vomiting ceased in a few days but the diarrhœa continued for a week and the temperature remained at from 103° to 104°, while great pain was complained of in the abdomen and left chest. There was also jaundice for a few days during the first week of her illness.

When I first saw the patient on Sept. 21st her great complaint was the severe pain which she was suffering in the abdomen; this came on in paroxysms and was evidently very severe. There were marked tympanites and great tenderness all over the abdomen. In the left chest there were signs of consolidation in the lower two-thirds of the lung posteriorly, with bronchial breathing and consonant râles. There was also a patch of pneumonia at the extreme base on the right side. The respirations were rapid, the temperature was 101°, and the pulse was 140. I must confess that I thought very badly of the case, looking upon it as one of "pneumococcal peritonitis" with double pneumonia. On the other hand, her general condition was wonderfully good considering the extent of the inflammatory lesions. She was bright and cheerful when not in pain; the vomiting had ceased; her features were not drawn, nor were there any signs of collapse. The next 12 days produced no improvement and when I saw her a second time (on the twenty-third day of her illness) it was clear that the abdomen contained a large quantity of fluid; the flanks were bulging and a well-marked fluid thrill could be obtained from side to side. The superficial veins were distended and a zone of redness was present around the umbilicus. The left pleura was full of fluid, being dull on percussion, and the heart was pushed over to the right. The patch of pneumonia present on the right side at the last examination had disappeared.

Operation was at once decided upon and Mr. G. A. Wright next day evacuated 40 ounces of pus from the abdomen by inserting a tube at the umbilicus, but before his arrival the pus had penetrated the skin at this spot and some had escaped. A rib was excised and the empyema was drained at the same time. Much pus drained away from the tube in the abdomen during the next few days but it ceased to flow before the end of the week and the tube was removed. The draining of the empyema was a more tedious affair but a good recovery eventually resulted.

Dr. W. J. S. Bythell was good enough to make a very careful examination of the pus and also cultures in Professor S. Delépine's laboratory. He reported as follows:—"Peritoneal pus was thick and viscid, not settling into layers; pale greenish grey colour, inodorous. Microscopically, richer in cells than in fibrin; crowded with cocci which were arranged in tetrads and capsulated, staining extremely good, but capsules not coloured by eosin. A careful examination of 10 slides failed to reveal any pneumococci. Phagocytosis very good. No tubercle bacilli. Vigorous cultures of micrococcus tetragenus obtained on agar and gelatin, the latter without liquefaction; films well stained by Gram's fluid. No colonies of pneumococcus. Empyemic pus, on standing, deposited a greyish green precipitate, supernatant layer clear amber colour. Microscopically, richer in fibrin than in cells; a small number of pneumococci, varying a good deal in size, and staining reactions; no chains. A few capsulated cocci, arranged mostly in pairs with a few tetrads. Phagocytosis moderately well marked. No tubercle bacilli. Cultures on agar, small isolated colonies of (*a*) typical pneumococci, (*b*) large and opaque colonies of micrococcus tetragenus. Gelatin stab cultures were characteristic and without liquefaction."

This was in many ways a remarkable case and the complete recovery which took place with such inflammatory lesions was certainly surprising. When first seen the case looked like one of "pneumococcal septicæmia" associated with general peritonitis and double pleuro-pneumonia and the prognosis seemed to be of the gloomiest. But at no time was there any very marked collapse such as would have been expected and the vomiting after it ceased during the first week was not again troublesome.

What was the significance of the micrococcus tetragenus in this case? It is apparently often found in suppurations about the neck and respiratory tract. Dr. Bythell tells me that he has found it four times in the pus of empyemata (out of 40 examinations), but in association with the pneumococcus in all four cases and once or twice with other cocci as staphylococcus aureus. I am not aware that it has been noted before in the lymph or pus of peritonitis. In this case it was associated with an inflammation which ran its course without producing the grave constitutional symptoms which one would naturally expect, but whether this coccus produces a milder inflammation than most other cocci it is not possible to say.

Which serous membrane was first affected? The peritoneum or pleura? As far as the evidence goes they commenced simultaneously and there is no evidence to show which was primary.

Was the peritonitis really pneumococcal in origin, the organism perishing before the pus found its way out, as the peritonitis had been in progress for some 23 or 24 days before any bacteriological examinations were made? Certainly the case closely resembles one type of pneumococcal peritonitis as described by M. Broca.[3] This author publishes three cases very similar clinically to mine in which the pneumococcus was present in the pus. In one of his patients the symptoms of peritonitis followed a day or two after the crisis of an apical pneumonia, in the other two the symptoms of the peritonitis came on without being preceded or accompanied by any pulmonary lesion, but one of these patients died from a post-peritoneal broncho-pneumonia; the other two patients recovered. The symptoms in all three came on suddenly with vomiting, diarrhœa, fever, and pain in the abdomen; in a few days there was obviously a collection of fluid in the abdomen, redness appeared at the umbilicus, and there was a discharge of pus at this spot. The author points out that this rapid formation of pus and "fistulisation rapide de l'ombilic" is characteristic of a pneumococcic peritonitis and that such cases are liable to be confounded with acute enteric fever, tuberculous peritonitis, or appendicitis. M. Broca also reports a case in which there was a local collection of pus in the abdominal wall and a case of diffuse general peritonitis which was rapidly fatal, both of which were pneumococcal. This last case appears to have resembled the case of Dr J. H. Bryant which was reported in vol. i. of the Transactions of the Society for the Study of Disease in Children.

[3] Péritonite à pneumocoques, par M. Broca, Gazette Hebdomadaire de Médecine et Chirurgie, Oct. 21st, 1900; abstracted in the Archives de Médecine des Enfants, May, 1901.

It is interesting to note that all seven of the cases referred to above were in girls. This may be only a curious coincidence; or is it possible that the infection may take place, like a gonococcal infection, from the vagina to the peritoneum? My above cases illustrate the well-known observation that prognosis is very difficult in peritonitis; the most promising cases often go unexpectedly to the bad, while every now and again a seemingly inevitably fatal case makes a good recovery

I must express my great indebtedness to Mr. Senior of Levenshulme for his notes of the case and to Dr. Bythell for his careful examination of the pus

Manchester.

TWO CASES OF PARALYSIS AGITANS IN THE SAME FAMILY, IN WHICH IMPROVEMENT FOLLOWED THE ADMINISTRATION OF HYOSCINE.

BY JUDSON S BURY, M.D LOND., F R.C.P.,

PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY.

IN the following cases the chief points of interest are (1) the presence of typical symptoms of paralysis agitans in a brother and a sister; (2) the onset of the symptoms at a comparatively early age; and (3) the improvement which followed the administration of hyoscine during each of the two periods when it was given

The patients first entered my wards in the Manchester Royal Infirmary on Sept. 17th, 1900, and remained under treatment for 11 weeks. They were readmitted on Dec. 31st, 1901, and left on Feb 5th, 1902. The man, 41 years of age, was formerly a mill spinner but he was obliged to leave off work at the age of 35 years owing to weakness in his legs and a tendency to fall on to his face. These were the earliest symptoms to attract his attention. A year later he noticed that his legs were shaking; after a few months his arms began to tremble and subsequently he noticed that his head shook at times. He attributed his condition to working in a very hot room and then going out into the cold. His sister stated that her illness began when she was about 18 years old. The tremors came on so gradually that she could not be sure when they actually commenced, but at the age of 19 years they were so bad that she was obliged to give up her work in the mill at which she had been engaged for several years. She attributed her illness to her occupation, which involved the constant contact of her hands with wet and cold yarns. Neither in the case of the brother nor in that of the sister could any history of fright, or injury, or previous illness be obtained. The father of these patients was asthmatical; they did not know the cause of their mother's death One brother died from consumption at 24 years of age and another brother died from influenza. They stated that two sisters had suffered from paralysis agitans but no confirmation of the statement could be obtained, one of these sisters died at the age of 16 years and the other at the age of 26 years.

Both patients presented the characteristic mask-like face, attitude, tremors, and other symptoms of paralysis agitans. In both cases the tremor affected the hands and forearms, the feet, and to a slight degree the head; in the man the legs also shook as they lay extended on the bed. The tremor affected the hands much more than other parts; it could be controlled by a voluntary effort; it was absent during sleep, very slight on waking in the morning, and worse towards night or after any exertion. It was not symmetrical on the two sides; thus, the man's left hand trembled more than his right hand. The movements of the limbs were weaker than natural. The weakness was irregularly distributed; thus, the grasp of the man's right hand was weaker than that of his left, while the muscular power of his left leg was weaker than that of his right. Slowness of movement, however, was perhaps more conspicuous than weakness. This was especially noticeable as regards the head movements. Thus, when either patient looked to one side the eyes turned quickly but rotation of the head was slowly performed. The muscles of both arms and legs showed increased irritability to tapping As regards muscular stiffness in the limbs this was slight or absent; in the man no rigidity of limb could be detected, in his sister the muscles of the forearms appeared to be a little more rigid than normal. The fingers did not occupy the usual "interosseal" position but were slightly bent at all the joints. It is to be noticed that in both cases the little fingers presented a congenital deformity, their first phalangeal joints being rigidly flexed owing probably to shortening of their tendons. Both patients presented the characteristic stooping attitude In walking the man showed a slight tendency to hurry forwards, while in the woman there was a marked tendency to retropulsion. A very slight push on the chest made her walk backwards; the pace increased at each step until she lost her balance and fell into the arms of the nurse walking behind her. In both patients the knee-jerks were exaggerated and in the man a true ankle clonus was obtained on several occasions; sometimes it was absent. No indications of ataxia or of sensory disturbance could be detected and the skin apart from flushing and sweating presented a normal appearance.

The patients were treated by massage and by the administration of hyoscine. At first this drug was given hypodermically, the dose being gradually increased from $\frac{1}{200}$th to $\frac{1}{150}$th of a grain, which was injected once a day. As the larger dose produced nausea, dryness of the mouth, and giddiness the injections were discontinued. Subsequently hyoscine was given in chloroform water by the mouth, as recommended by Dr. R. T Williamson At first $\frac{1}{192}$th of a grain was given twice daily This dose was gradually increased to $\frac{1}{64}$th of a grain. Both patients took this amount without any ill effects and while they were taking hyoscine in this way they appeared to be much better They stated that they felt more comfortable and were less troubled than formerly with flushings and restlessness. The tremor became less marked, as shown in tracings taken before the administration of hyoscine and again after the drug had been taken for some time. Dr. A. Ramsbottom (my house physician) and others who had watched the cases thought that the attitude and gait were also improved by the treatment.

Judging from an experience of several cases I am inclined to agree with my friend Dr. Williamson that hyoscine is probably the most useful drug that has hitherto been tried in the treatment of paralysis agitans. As a rule, it diminishes or arrests the tremor, checks the troublesome restlessness and the desire to change position, and relieves the "hot flushes" and unpleasant sensations of heat. It is important to remember that hyoscine is a very powerful drug and hence must be administered with great care It is safer to give it by the mouth than to inject it under the skin Merck's hyoscine hydrobromate is probably the best preparation, this should be given well diluted in chloroform water "A prescription which is useful is one-eighth of a grain of hyoscine hydrobromate in six ounces of chloroform water At first two teaspoonfuls of this may be given, then three, four, or five teaspoonfuls. If necessary the dose may be increased to six teaspoonfuls ($\frac{1}{64}$th of a grain), providing toxic symptoms are not produced. The hyoscine is best given in the morning, just after breakfast, and again in the evening (just before going to bed) if the patient is troubled with restlessness and sleeplessness during the night."[1]

ON CARDIAC INADEQUACY.[1]

BY ALEXANDER MORISON, M.D., F.R.C.P. EDIN.,
PHYSICIAN TO OUT-PATIENTS AT THE GREAT NORTHERN CENTRAL HOSPITAL; PHYSICIAN TO THE CHILDREN'S HOSPITAL, PADDINGTON-GREEN.

BY the term "cardiac inadequacy" in the sense in which I purpose employing it on this occasion I do not mean inadequacy of the heart from valvular defect, nor have I in my mind that form of inadequacy due to muscular degeneration of the walls of an otherwise normal organ. I refer to a form of inadequacy the existence of which can, perhaps, at present be suggested rather than proved and which need not be associated with histological change of texture but which may, of course, also be concurrent with such. The use of the term may, indeed, be regarded by some as but a cloak for ignorance. It will, however, I think, be found on consideration to be justifiable and it is, moreover, one which has not been left unemployed, although it may require further definition and elucidation. The late Sir Andrew Clark used to speak of a "renal inadequacy" in kidneys which in some instances on anatomical examination were apparently normal, but in which the average functional activity of the organs was subnormal.[2] We know, moreover, from Dr. J. R. Bradford's convincing experiments[3] that a very considerable diminution may be effected in the size of the kidneys without endangering the life of the animal experimented upon, for the remaining renal texture tends to enlarge to cope with the additional work thrown upon the remainder of the organs. The minimum of healthy renal texture compatible with life may, however, be approximately determined by the excision of portions, and then an actual renal inadequacy without disease of the secretory structure is established. Similarly, no doubt, the minimum of any other secretory organ essential to its functional adequacy might also be determined, provided the operation to diminish its bulk were not in itself destructive of life.

In the case of the heart we have to deal with a purely mechanical organ, an aspirative and propulsive pump the functional adequacy of which is largely proportionate to the muscular power of its walls and a due preservation of the proportion between these and the chambers contained by them, although other factors, with which I shall not deal on this occasion, also go to produce the functional adequacy of the organ. It is, perhaps, scarcely necessary to recall the fact that the heart bears a certain relation to the size of the animal which contains it. The heart of an ox is larger than that of a sheep, of a cat than that of a rat, and that of a rat than that of a mouse. In the human subject the heart of an average man weighs more than that of an average woman, of an adult more than that of a child, of a big man more than that of a little man. This is the rule, to which there are occasional exceptions and the exceptional conditions may have important consequences.

According to Reid[4] the average weight of the heart of the adult male is 11 ounces and of the adult female nine ounces. Peacock[5] places it somewhat lower—namely, at nine and three-quarter ounces for the male and at nine ounces for the female. "Inasmuch," writes Walshe, "as the heart varies very sensibly in bulk with the stature and mass of the whole body, and also with the age of the individual, it follows that a general standard applicable with moderate precision to all persons, even of the same sex, is not attainable."[6] For practical purposes he assumes the average weight of the healthy male heart to be nine and a half ounces and of the female organ eight and a half ounces.[7] Hamilton's more recent average, as given by Gibson,[8] is from 10 to 13 ounces for men and from 10 to 11 ounces for women. "His results," says Gibson, "show, as was previously expected, that there is no real ratio between the size of the body and that of the heart; yet they indicate that, as a rule, the heaviest hearts are to be found in the tallest persons."[9] These calculations are avowedly made from the dead heart. It may be possible, however, hereafter, as will be presently suggested, to determine this matter more precisely in the living. A statistical determination of this point from the cadaver is open to fallacy, unless the height and body-weight of each individual be determined at the same time and a sufficient number of hearts of persons of the same general height and weight be compared with one another. Care should also be taken in such a calculation that the organs which are weighed have approximately the same amount of extraneous material attached to them when the weight is taken. I question very much whether all these points have ever been so carefully observed in a sufficient number of cases as to afford a reliable calculation. The fact may, however, be accepted that the larger the animal, whether biped or quadruped, the larger, as a rule, is the normal heart necessary for an adequate propulsion of its circulation, and one may assume for practical purposes that the average weight of the heart of an adult man may be placed at 10 ounces. That accurate observer, Allan Burns of Glasgow, so much of whose work is still valuable, remarks that "in some instances the heart is so diminutive as to bear no proportion to the sanguiferous system. In one case on opening an adult body, with the history of which I was unacquainted, I saw the heart little larger than it is often met with in a new-born child. In another instance I found the heart of a female, 28 years of age, no larger than the same organ usually is in a girl of six. In the preparation the heart appears healthy in structure. The vessels are of a size proportioned to the age of the subject but no more."[10] Such instances of excessive cardiac hypoplasia, while most interesting, must be very rare. Everard Home states of the heart of John Hunter that "it was very small, appearing too little for the cavity in which it lay."[11] The pericardium was thickened and did not collapse on section. This fact recalls a wise caution of of Allan Burns—namely, that "we ought never to consider a heart as reduced in size unless at the same time the pericardium be diminutive."[12] This is true, no doubt, of congenital hypoplasia, but an atrophied heart may occupy a pericardium of normal dimensions. The very difficulty which has been experienced in establishing a definite relation between the size of the organ to the organism in the human subject rather emphasises the importance of drawing further attention to the matter than of leaving it unconsidered. For while a smaller organism may not be materially inconvenienced by the possession of a relatively large and healthy organ it is conceivable that a large organism may suffer from the presence of one too small for its purposes.

The weight of the normal heart being chiefly due to the amount of cardiac muscle which it possesses, heart-force may be roughly stated to be proportionate to heart-weight unless some palpable defect in the organ renders its muscular advantage nugatory. We are justified, I think, in believing this to be the rule, but it is possible that mere bulk, even without gross disease, may in some cases be associated with an essential functional inadequacy. For the functional adequacy of the heart—as, indeed, of all the organs of the body—is the expression not of one but of three factors. In the case of the heart these are muscle, nerve, and blood, and to secure functional adequacy these factors, moreover, must exist in that harmoniously balanced state and proportion the result of which is vigorous vital motion.

The evidences of a due aspiration and propulsion of the circulation are to be found in the absence of excessive overflow into the textures of the body outside the vascular system—that is, in the proper emptying of the veins and in the maintenance of a steady average moisture in the lymphatic vessels and their associated spaces, such as the pleuræ, the pericardium, and the peritoneal cavity. Local circumstances, systemic, pulmonic, or portal, may account for local *stagnation* in the venous and lymphatic systems apart from the influence of the central organ of circulation, but clinical experience, I believe, justifies the opinion that the influence of local impediments is exaggerated by a diminution of the power of the heart and lessened by an increase in that power. We frequently observe cases in which practically the same local conditions are associated, in some cases with more, in others with less, evidence of venous and lymphatic overflow. This experience likewise holds good as to the results of treatment.

[12] Op. cit., p. 110.

Thus the removal of effusion in some cases is followed by cure or a long immunity from recurrence. In others, which are mechanically indistinguishable from the former at the bedside, treatment is baffled by a rapid reappearance of retrogressive phenomena or by greater difficulty in establishing a due relation between the forces which propel the circulation and those which tend to retard it It seems, indeed, probable that the varying success of the physician in securing cardiac "compensation" for disabled action (and this apart altogether from the nature and situation of gross mechanical lesions) is influenced by an essential or congenital difference in hypertrophic power—in a word, in greater cardiac adequacy on the part of one heart as compared with another. Like the poet, the highly recuperative organ is born, not made, but careful management may do much for a radically inferior heart, just as similar care may result in the production of a very passable poetaster. It would be hazardous to fix upon any single circumstance as turning the scale in favour of or against a patient in some cases. It has been argued that functional adequacy is the result of at least three factors, not of one, and the influence of such circumstances as the age, the general organic condition, and the reserve force of the patient cannot be lost sight of.

The two cases which I wish presently to bring before the notice of the Æsculapian Society this evening, however, seem to argue that there is one circumstance in this connexion which has not, so far as I know, been sufficiently emphasised, or, if it has, has been practically forgotten, but which is nevertheless calculated to have an important bearing on the life of the patient and, *ceteris paribus*, on the success of treatment. That circumstance affects the muscular factor in cardiac adequacy and is expressed by an abnormal smallness of the heart in proportion to the circulation which it is called upon to maintain. It is well known that in a certain number of cases of phthisis the heart is found on examination after death to be below the average size and there have been some who have inclined to the belief that there was a connexion between the smallness of the heart and the diseased condition of the lungs. Many consider, however, that this conclusion is an instance of placing the cart before the horse and that the exhausting processes of the pulmonary malady are the more direct causes of the diminution in size or atrophy of the heart. The fuller consideration of this point does not, however, arise at present. It will be shown, moreover, that in those cases which I am about to relate and which were also examined after death smallness of the general size of the organ was associated with hypertrophy of its walls, a circumstance which excludes the agency of atrophic and degenerative processes. It may be remarked, however, in this connexion that Walshe[11] writes as follows: "It may be that a phthisical individual whose heart only reaches the par of health for his age and sex is nevertheless clinically the subject of hypertrophy; his amount of heart is beyond the legitimate wants of his impoverished system." If, therefore, it can be shown that the heart may be too small for the work it has to accomplish it is manifestly important that such a fact should be capable of detection in the course of clinical investigation. If it be possible to detect enlargement of the heart it should also be possible to detect dimensions less than those usually met with and by the means ordinarily employed. That it is possible by such means cannot be denied On the other hand, diminution of the heart below the normal size is not clinically so striking as enlargement beyond such average. The resonant conditions and varying shape of the præcordial thorax, moreover, are calculated to mask other than well-marked variations In one of the cases to be presently related the apex beat was in the fourth left intercostal space and at, not beyond, the nipple line, but I confess that the diagnosis of an abnormally small heart was made only in the deadhouse. In the second case related the small heart was displaced by the subdiaphragmatic tension of the ascitic fluid and in that case also the discovery of the small heart was left to the pathologist. These facts, however, do not in any way remove the possibility of the discovery of a disproportionately small heart by the ordinary processes of inspection, percussion, palpation, and auscultation. We have, however, now a surer method of coming to a conclusion on this point by the accurately measured use of the Roentgen-ray apparatus. In all photographic processes the value of the resulting picture would be greatly enhanced by the routine use of a readable scale on such pictures; I shall presently show how an ordinary tape measure may be utilised for this purpose. But a scale drawn across the face of the fluorescent screen in Roentgen radioscopy or exact measurement of the shadow in Roentgen radiography would give an approximately correct idea of the dimensions of the portrayed shadow. If, further, the distance of the light from the body and the antero-posterior dimensions of the thorax examined were similarly measured, under the same circumstances as to time, feeding, and posture, we could form a sufficiently correct idea of the size of the organ casting the shadow By this means, then, the height and weight of the organism being known, data could be collected to determine whether a given normal heart was above or below the normal size.

When a heart essentially inadequate gives way under the strain of ordinary existence or exceptional effort, or in consequence of acquired impediment from disease affecting any portion of the circulatory system, the persistence, rapid onset, and intractability of the conditions induced may be expected to be characteristic of the essential and original fault. But perhaps the most delicate index to imperfect blood-pressure is the amount of the urine—that is, of water voided by the kidneys. The secretory structure proper to these organs may be healthy and the output of solids not apparently lessened, but the urine will have a high specific gravity and proportionately deposit a larger amount of solids Such a condition may, of course, result and, as we know, does result, when a heart, however originally adequate, breaks down from any cause; but when such failure is supplemented by an essential inadequacy it may be expected to be a still more marked, and perhaps more easily detectable, sign For the rest the essentially inadequate organ must participate in all the recognised phenomena indicating failure of the heart from any cause whatever.

With these preliminary observations I shall now endeavour to answer the question whether there be or not an essential cardiac inadequacy. If the question be answered in the affirmative it will necessarily imply the existence likewise of an essential cardiac *adequacy* which may manifest itself under circumstances of mechanical or other strain placed upon the energies of the heart. To answer the question rationally the hypothesis suggested must be submitted to the touchstone of fact; I must relate instances of its occurrence and I purpose considering on this occasion the influence of diminished bulk of muscle in the heart or disproportionate smallness of the organ, of which the following case was a good example.

CASE 1.—A man, 57 years of age, was under my care at the Great Northern Central Hospital. He had been a policeman. He was admitted on May 7th, 1901. About a month previously he had noticed swelling of the abdomen and experienced dyspnœa on exertion. He looked more than his age, was sallow and somewhat emaciated, was rather above the average height, and the peritoneal cavity was filled with fluid. His legs, also, were œdematous His pulse-rate was 80; it was regular, rather large, and easily compressible. The apex beat of the heart could neither be felt nor seen. Its left percussion line was within the vertical nipple line and its right reached the mid-sternum. The first sound was very soft and weak and the second was short and unaccentuated There was no bruit. The percussion note over the bases of both lungs was slightly impaired and there were fine and medium-sized râles over the bases of both lungs posteriorly Vocal fremitus was normal The urine had a specific gravity of 1025; it showed a heavy deposit of lithates but contained neither albumin, blood, nor sugar. Rest in bed was at first followed by considerable increase in respiratory and general comfort but had no appreciable effect upon the ascitic tension of the abdomen. On the 17th 200 ounces of fluid were withdrawn from the abdomen by paracentesis. The parietes being lax thereafter the abdominal cavity could be examined by palpation but no induration of liver or other abnormality could be detected. The urine continued normal in character though not in quantity. On the 30th 180 ounces of fluid were removed by tapping Next day I determined the following points in connexion with the patient's heart. The apex beat was apparently just above the fourth rib and at the nipple which was four inches from the mid-sternum There was dense percussion dulness below that point running without modification of note into the liver dulness. On June 4th the ascitic fluid was again noticed to be reaccumulating and on the 13th 260 ounces were removed. The condition of the patient was now steadily deteriorating and jaundice became well marked. On the 20th 260 ounces of fluid were removed by paracentesis abdominis and the same quantity was again withdrawn on the 26th. The patient died on July 3rd. The average quantity of urine passed by him during his illness, and estimated from 32 diurnal collections, was about 24 ounces, the highest record being 42 ounces, and the lowest nine ounces, for 24 hours.

---

[11] Op cit., p. 16

On post-mortem examination the abdominal cavity was found to be full of icteric fluid. The liver was enlarged but on microscopic examination showed no overgrowth of interstitial tissue. The spleen was also large and its pulp was soft. The kidneys were large and had adherent capsules. The pancreas was hypertrophied and in places hard but gave no evidence of tumour or malignant growth. The stomach and intestines were normal. The heart was abnormally small, weighing only seven and a half ounces. Its ventricular walls were hypertrophied, the left in its greatest thickness measuring three-quarters of an inch, the septum rather more, and the right ventricle at its thickest point about half an inch. The cavities of the heart were relatively small and all the valves were normal. On microscopic examination the muscle bundles were found to be separated by an excess of interstitial tissue and here and there the muscle fibres showed a fine fatty degeneration. The lungs were somewhat shrunken, the left being œdematous and at its apex adherent, where there was a focus of pneumonia. The pleural cavities contained no excess of fluid. In this case, notwithstanding a record in the notes of the necropsy of adherent capsules on the kidneys, there was no reason to regard those organs as diseased and the absence of interstitial changes in the liver likewise excluded a strangling of the portal circulation as the cause of recurrent ascites or cardiac hypertrophy. The small hypertrophied heart, therefore, may be legitimately regarded as the evidence of an originally inadequate organ of otherwise healthy constitution, coping for a time successfully with a task beyond its capacity and ultimately yielding to its overwork, prematurely ageing, and finally causing the death of its containing organism.

J. McS.—Longitudinal section of the heart from behind showing the left ventricle to the left [illegible] a large adherent ante-mortem clot in the right auricle.
G. P.—Longitudinal section of the heart from the front, showing the left ventricle to the right.
The tape scale shows the measurements.

In the following case a similarly inadequate heart was not the primary cause of the phenomena which marked the decay and death of the organism, but it may, I think, be rationally regarded as having aggravated the fatal conditions. The heart was again small but hypertrophied.

CASE 2.—A man, 33 years of age, was under my care at the Great Northern Central Hospital. He was admitted on Sept. 17th, 1901, suffering from dyspnœa and peritoneal dropsy. He was a thin, feeble looking man, rather over the average height. His father had died from heart disease but there were no other points in his family history, as given by the patient, to call for comment. He himself had been a soldier in India and had suffered repeatedly from fever and ague. He denied both alcoholic excess and venereal infection. His temperature ranged from 97° to 99° F. and his pulse-rate from 72 to 100. The following note was made of the condition of the heart on admission: "Cardiac dulness begins at the third rib above; it does not extend to the right beyond the right edge of the sternum, but there is some definite dulness to the left beyond the nipple line. No murmurs are detected." The lungs were equally resonant on percussion on both sides and scattered rhonchi were the only abnormal sounds heard in either organ. His urine was scanty, of high specific gravity (1030), and it contained an excess of urates but neither albumin nor sugar. The peritoneal cavity was filled with free fluid and so distended as to prevent an examination of the abdominal organs by palpation. On the 18th 187 ounces of fluid were removed by paracentesis. The fluid was clear and yellow, had a specific gravity of 1010, and was two-thirds albuminous. The abdominal organs could now be palpated and the spleen was found to be greatly enlarged, its lowest point being detectable just above the left iliac crest and its anterior edge displaying a well-marked notch. Beyond this nothing definite was noted. The urine remained scanty and loaded with urates but free from albumin and the ascitic fluid gradually reaccumulated until Oct. 5th when 90 ounces were removed by tapping. On examination the patient's blood showed 75 per cent. of hæmoglobin, 4,300,000 red cells, no poikilocytosis, and 6250 white cells, the majority of which were polynuclear. After paracentesis the patient was more comfortable but his general condition was unsatisfactory. On the 6th he had slight hæmoptysis; on the 7th the abdomen was strapped to retard the reaccumulation of fluid; on the 8th the visible impulse of his heart was noted as having been in the fourth and fifth spaces and the area of cardiac dulness as four and a half by four inches, and the heart's beat was regular and without bruit. On the 11th palpable and audible coarse friction was detected over the enlarged spleen and the patient lost a little blood by the bowels. On the 30th 100 ounces of fluid similar in character to that previously examined were withdrawn. The patient complained a good deal of pain in the abdomen (? peritonitis) and required hypodermic injection of morphia for relief. Dulness over the bases of the lungs posteriorly was also detected and the respiratory sounds were somewhat masked. As the abdominal strapping appeared to aggravate discomfort it was removed on Nov. 12th and on the 25th 152 ounces of fluid were withdrawn by tapping. The splenic condition varied very little and the hard edge of a cirrhotic liver could now be felt in the upper portion of the epigastrium. The enlargement of the spleen was therefore regarded as mainly due to hepatic strangling of its circulation, with the possible addition of an old malarial element. The patient expressing a desire to go home for a few days and his home being close at hand he was permitted to leave the hospital and advised to return at once if he became in any way more embarrassed. He was readmitted on Dec. 2nd, having had hæmatemesis to a large amount the night previously. He looked rather blanched. He had a pulse of 120 and a temperature of 99·4°. The abdominal dropsy had recurred. As the patient had been tapped and strapped with ever recurring dropsy so frequently I asked my colleague, Mr. Peyton T. B. Beale, to empty thoroughly the peritoneal cavity by peritoneal section. This was accordingly done on the 3rd but no attempt was made to stitch the omentum to the parietal peritoneum or to establish adhesions by peritoneal friction, as has been practised by some surgeons. The patient rallied well after the operation but had recurrence of hæmatemesis to about a pint next day. This was checked by the use of 10 minims of a solution of suprarenal extract (20 per cent.) in an ounce of hot water. On the 5th there was again a recurrence of the bleeding which also was checked by the use of suprarenal extract. Next day the patient died exhausted. The average daily output of urine in this case, estimated from 73 separate collections was 20 ounces, the largest quantity recorded during 24 hours being 42 ounces and the lowest six ounces, while on a considerable number of occasions the quantity measured was well below 20 ounces.

The body was examined post mortem on the 6th. The peritoneal cavity contained over 70 ounces of thin sanious fluid with a few coagula of blood and some flocculi of fibrin. The peritoneum itself was thickened throughout and opaque. The liver, spleen, stomach, gall bladder, and large intestine were matted together by old adhesions and in a measure by newly formed fibrinous deposit. The liver was small, hard, hobnailed, and fatty on section. The interstitial tissue was much increased. The spleen was greatly enlarged and almost inseparably connected with the stomach by old and new adhesions of varying consistency. The stomach was catarrhal and congested and contained some blood clots. The intestines were also affected by catarrh and were congested. The kidneys were somewhat swollen and cyanosed, their parenchyma was fatty, the capsules were adherent in places, and the organs were lobulated. Both lungs were adherent posteriorly, collapsed, and affected by hypostatic congestion. The right pleura contained 28, and the left 46, ounces of a sanious flocculent fluid. The heart was remarkably small, weighing, with the usual amount of extraneous vessels attached and the intra-cardiac clots, eight ounces. It was normal as to its valves. The ventricular walls were hypertrophied, the left at its thickened part, including the section of a papillary muscle measuring one inch and the septum three-quarters of an inch. A large decolourised clot was adherent to the wall of the right auricle and a smaller one of the same character occupied the conus arteriosus. On microscopic *examination there was some, but not much, increase of inter*stitial tissue and the muscular fibre and vessels were normal.

These two cases, then, as they were observed for a considerable period during life and were examined carefully after death, will serve to illustrate the point which I wished to submit to the society this evening, whether they be regarded as sufficiently establishing that point or no. The time at our disposal prevents a consideration of the influence of failure in the nerve and blood factors in cardiac inadequacy which may impair the efficiency of a heart otherwise well proportioned to the size of the body which it has to serve. Nor have we time to illustrate the contrary condition of essential cardiac adequacy—if that be a justifiable term. By bearing in mind, however, this underlying adequacy or inadequacy in cardiac action as the case may be, and which I believe to be essential qualities of the organ, I contend that we shall find the key to some of those circumstances of success or failure in the management of diseases and disorders of the heart which so frequently afford food for thought. It may likewise in some measure serve to explain why the secondary phenomena of cardiac failure in distant parts of the body should manifest themselves in some cases, while in others much resembling these such phenomena are absent or transient, sometimes more, and at other times less, amenable to treatment.

Upper Berkeley-street, W.

ROYAL DENTAL HOSPITAL OF LONDON.—It is announced that a special *matinée* will be given at Queen's-gate Hall on Friday, May 2nd, in aid of the above institution. A triple bill of original plays will be presented. The company engaged is a purely professional one.

PYREXIA OF GASTRO-INTESTINAL ORIGIN DURING THE PUERPERIUM

BY ETHEL M. N. WILLIAMS, M.D. LOND.

IT is a commonplace to say that many of the slighter cases of fever during the puerperium are due to disturbance *originating in the gastro-intestinal tract, but few people* would feel happy in regarding as of purely gastro-intestinal origin cases in which the temperature rose to 103° or 104° F., with a pulse of from 120 to 140. The picture in most minds when we speak of fever originating in the alimentary tract during the puerperium is of a moderate fever of from 100° to 102° occurring about the third day with little or no quickening of the pulse and little or no constitutional disturbance—the whole thing vanishing as soon as the bowels are satisfactorily opened. Most people, I think, hold that any marked quickening of the pulse up to 120 or more, especially when accompanied by high fever, is strong evidence of ordinary septic infection. The two following cases, if they are to be regarded as of gastro-intestinal origin, show that such infection can assume a much graver aspect. The first was a pure sapræmia, though a severe case; the second was of special interest owing to the rash which was such a marked feature. Certainly in the past such a case would have been labeled "puerperal scarlet fever," though the rash only in parts resembled the rash of scarlet fever and there was never any sore-throat or typical condition of the tongue.

CASE 1.—In the case of this patient, a married woman, aged 27 years, 2-para, labour began about 1 P.M. on August 6th, 1901. The vertex presented and the patient was delivered normally of a female child at about 4.30 P.M. There was no tear. The pulse was 96 at the time of delivery and it did not fall in rapidity, though the uterus contracted well and there was no loss. The patient complained of irritation and soreness about the anus and there were some reddening of the skin and scalding in the neighbourhood. She said that the bowels had been opened daily throughout the pregnancy, though the motions were generally hard. On the second and third days after delivery the temperature was normal and the pulse-rate ranged from 96 to 100. On the 8th an ounce of castor oil was taken early in the morning but the bowels did not act till late in the day. There was a great deal of milk which flowed away freely from the breasts. Late on the evening of the 10th the patient began to complain of abdominal pain and headache. When seen at about 9 A.M. on the 11th the temperature was 103·6° and the pulse was 120. She had not slept at all during the previous night. The tongue was moist and was covered with white fur and there were much headache and abdominal pain which seemed to be worst about the umbilicus. The abdomen was soft, it moved normally with respiration, and there was no tenderness except possibly in the upper part. The uterus was hard and involution was proceeding satisfactorily. The lochia were quite normal. There was much complaint of pain and of burning about the anus and the skin was markedly reddened to some distance from the orifice. A large enema of soap and water with two ounces of turpentine was given. This brought away some hardened fæces and a great deal of flatus. An intra-uterine douche was also given which brought away nothing. *A mixture containing two grains of* sulphate of quinine and 20 minims of liquid extract of ergot was ordered to be taken every six hours. In an hour the temperature had fallen to 101°. When seen at 6 P.M. the temperature was 103·8°, the pulse was 132, and the respirations were 30. There was a good deal of headache but the abdominal pain and anal scalding were much less. The tongue was moist and was covered with thick white fur. Milk was still being secreted, though in much lessened quantity. An enema of two litres of a dilute solution of creolin was given from a fountain douche. A large amount of fæces and much flatus came away. In an hour the temperature had fallen to 101·6°. The bowels were opened four times during the night. On the 12th at 9.30 A.M. the temperature was 98·8°, the pulse was 112, and the respirations were 18. The anal scalding and headache had gone and the patient said that she felt quite well. At 6 P.M. the temperature was 98·8° and the pulse was 96. By the next day the pulse had fallen to between 70 and 80 and recovery from this point was quite uneventful.

CASE 2.—The notes of this case were given to me by Dr. Minnie Ethel Bowlby. The patient, a primipara, had suffered from constipation for three or four years but it had grown much worse during the pregnancy. Labour began about 5 A.M. on Nov. 12th. The vertex presented and the patient was delivered of a female child at about 1 P.M. The placenta was expelled. There was a small tear in the perineum and one stitch was put in. The pulse was 68. In the evening the temperature was 100° F. On the 13th the temperature was normal and the uterus was hard and there was no tenderness. On the 14th the temperature was 100°. An enema was given which brought away much fæces and flatus. The temperature after the enema was 99°. On the 15th the temperature was 100·6°, the uterus was hard, and the lochia were normal. There was some flatulence. There was no headache. A bright-red papular rash appeared over the abdomen and arms. During the day it spread all over the body. It was raised and well defined at the edges. There was no sore-throat. On the 16th the rash had increased and had become markedly polymorphic. In parts it consisted of large raised erythematous patches. On the arms it was papular and on the chest and abdomen it was punctiform. The colour throughout was bright scarlet. An enema was given with little result. The temperature was normal in the morning and 100° in the evening. On the 17th the rash was still more profuse and the face was œdematous. The patient had only passed urine once in 24 hours. Four grains of calomel were given and later an enema, with at first no result, but after a second injection an enormous amount of fæces came away. The temperature was 99·4° both morning and evening and the pulse was 88. On the 18th the patient had slept well and the rash was fading. The pulse was 88 and the temperature was 100 8°. After an enema there was again an enormous motion. The evening temperature was 101·6°. On the 19th the temperature was 99·8° and the rash looked much more like measles, only it was of a bright-red colour and very irritable. In the morning the temperature was 103·6° and the pulse was 124. The patient was said to have had a rigor. An enema was given with very little result. The lochia had almost ceased. On the morning of the 20th the temperature was 100·2°. The feet and hands were red and œdematous and were covered with a sudaminal rash. There was intense irritation. There were red marks like scalding around the mouth and eyes. The uterus was contracting normally, there was no tenderness, and the lochia had quite ceased. The urine was acid, containing no albumin, and there was a large precipitate of urates. The evening temperature was 102·2° and the pulse was 100. On the 21st the morning temperature was 99 8° and the pulse was 80. The œdema of the face and hands was much less marked, but the rash had come out thickly again over the abdomen. The evening temperature was 101·8° and the pulse was 100. There was an enormous motion after medicine and enema. On the 22nd the morning temperature was 99·8° and the pulse was 88. The face and lower part of the back had begun to desquamate. There was a small amount of discharge from the vagina on that day. The evening temperature was 101° and the pulse was 90. The patient was passing large quantities of urine. There was desquamation all over the body, mostly in fine dusty particles, but the feet and hands peeled in large flakes The bed was full of scales each morning. On the morning of the 23rd the temperature was 99 2° and the pulse was 72; in the evening the temperature was 100·2° and the pulse was 78. By the 25th the temperature had fallen to normal. On Dec. 5th the patient had a few dates. On the 6th there was some œdema of the face and the rash reappeared over the face and the neck. The temperature was 100·4°. On the 7th the temperature was 99·6° and there was a recrudescence of the rash upon the chest. From this point convalescence was uneventful, though the peeling continued till the end of December.

I have never seen any case of gastro-intestinal poisoning in which the rash has been so prominent a feature, but a patient whom I have attended in two confinements has on each occasion had a pulse of from 96 to 100 from the time of delivery up to that of the bowels being opened on the third day, while contemporaneously with the opening of the bowels a very irritable, bright-red, papular rash has appeared over the chest, on the flexor surfaces of the wrists, between the fingers, and on the insteps. One is reminded of the rashes sometimes seen after administration of an enema which must be attributed to the absorption of some poison from the intestinal tube It would be a matter of extreme interest in these cases to test the urine for the presence of ptomaines and to determine the proportion between the simple and ethereal sulphates in order to see if there was any evidence of an abnormal amount of bacterial action going on in the intestinal tube.

My reason for publishing these few notes is to suggest that the rôle of the intestinal tube in infections during the puerperium is wider than it is generally supposed to be. The first of my two cases was certainly sapræmic, though the infective material was not all got rid of by the first enema. I think that it is a question whether in the second case the infecting material had not gained a footing in the living tissues—possibly only in the walls of the intestine.

Cases both of septicæmia and pyæmia have been described in which the infecting organism has been found to be the bacillus communis and it is much easier to suppose that the infection in those cases has taken place through the walls of the intestine rather than through a wound in the genital tract. It is known, as a matter of fact, that during the puerperium the resistance of the body against microbic invasion is very markedly diminished. It is but natural, then, to suppose that this loss of defensive power will be as apparent in invasion from the intestinal tube as in the more usual invasion from the genital tract. It does not need for me to point out the importance of a prompt diagnosis between these cases and those of ordinary septic infection. I cannot find out any definite symptoms marking off these intestinal cases. Of course there will be absence of symptoms pointing to the genital organs and, in my experience, there are always much flatulence and a good deal of complaint of abdominal pain which is usually localised in the upper quadrants of the abdomen. There is by no means always a history of constipation, though in such cases as I have seen there has been evidence when the bowels were moved that there had been retention of fæces.

Newcastle-on-Tyne.

PRIMARY CARCINOMA OF THE AMPULLA OF VATER.

BY F. DE HAVILLAND HALL, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE WESTMINSTER HOSPITAL AND JOINT LECTURER ON THE PRINCIPLES AND PRACTICE OF MEDICINE IN THE MEDICAL SCHOOL, &C.

IN view of the rarity of primary carcinoma of the ampulla of Vater I think that it is desirable to put on record the following case.

I first saw the patient, a man, aged 46 years, on Oct. 6th, 1900, in consultation with Mr. G. W. Simpson of Lamberhurst. The patient stated that he had been quite well until the preceding August; then he had a febrile attack (the temperature was from 103° to 104° F. for two days), accompanied with pain in the head and limbs. The attack closely resembled influenza. After three or four days the temperature became normal and the patient suffered from itching and flatulence. About a week later he became jaundiced and he felt ill, but there was no vomiting, diarrhœa, or pain. This condition continued up to the time that I first saw him. On examination the thoracic viscera were found to be normal. The liver was uniformly and greatly enlarged, reaching nearly to the umbilicus, and the distended gall-bladder could be made out. The motions were clay-coloured and the urine was bile-stained. The temperature was normal. The patient had lost about two stones in weight since the commencement of his illness. Previously to the present illness the patient's health had been excellent; there was no history of enteric fever, pneumonia, or any other serious affection. He was ordered chloride of ammonium (20 grains) every six hours.

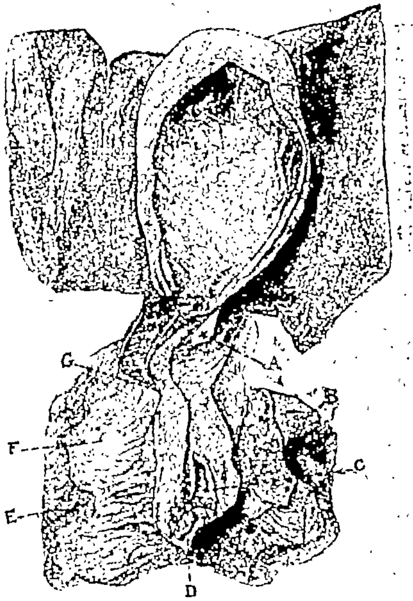
I did not see the patient again until he was admitted into the Westminster Hospital under my care on Jan. 5th, 1901. On admission he was deeply jaundiced. The liver could be felt three or four fingers' breadth below the costal margin; it was hard and rather tender and it appeared to be regularly enlarged. The gall-bladder was distended. The spleen could not be felt. There were no ascites and no œdema. The stools were semi-solid, clay-coloured, and very offensive. The urine was acid, bile-stained, and free from albumin and sugar. The temperature on admission was 98°. On the 7th it rose to 102·4°, falling next day to 97·6°, but there was another rise on the 9th to 104°. The patient became comatose at 4 P.M. on the 9th, having previously complained of severe headache for some hours. On the 10th the temperature gradually and steadily rose and at 5 A.M. on the 11th it was 107° and the patient died.

A necropsy was made eight hours after death by Dr. W. S. Lazarus-Barlow, when the body was found to be moderately nourished, with intense bronze jaundice. The hair was iron-grey. The lungs weighed respectively the right 32 ounces and the left 28 ounces, and were emphysematous anteriorly and congested with localised patches of semi-consolidation posteriorly over both organs. The larynx, the trachea, and the bronchi were congested and much mucus was found therein. The bronchial glands were large and soft; the pleuræ and the pleural cavities were normal. The pericardium contained bile-stained fluid. The heart weighed 12 ounces; it was flabby but fairly normal otherwise, the edges of the mitral flaps being rather thicker than normal. The great blood-vessels also were normal. No ascites was found in the abdomen. The liver weighed seven pounds; it was enlarged and of a deep green, almost black, colour. Its substance was fairly firm. The bile passages were much dilated throughout the organ. The gall-bladder was dilated and full of pale-green bile of a watery consistence. The cystic duct was much dilated and the common bile duct was sufficiently large to admit the little finger in its main course. At the papilla in the duodenum the orifice was of the normal size, but the whole papillæ and a small portion of the duct behind the opening were enlarged and firm, so that a mass of the size and somewhat of the shape of a small bean lay beneath the duodenal mucous membrane. The pancreatic duct was much dilated and bile could be made to flow through the unopened papilla by pressure on the gall-bladder. On slitting up the common duct from the papilla it was seen that there was a soft and ulcerating mass of material lying immediately within the orifice. From the surface of this a fluid having the appearance of pus could be scraped. The mass surrounded the entire lumen but did not extend further along the duct than about three-eighths of an inch and it did not invade deeper tissues. The tail of the pancreas was very dense but the head was of normal consistency. Wirsung's duct was dilated throughout. The spleen weighed 13 ounces; it was soft and large. The kidneys weighed respectively the right nine ounces and the left 13 ounces. They were highly congested and bile-stained and were apparently the seat of a tubal nephritis. The adrenals were normal, as also were the bladder, the stomach, the œsophagus, and the intestines.

Microscopically the growth was a columnar cell carcinoma. The position of the tumour and its relationship to surrounding parts is well shown in the accompaning illustration.

In THE LANCET of Feb. 16th, 1901, p. 467, will be found an excellent paper by Dr. H. D. Rolleston on Primary Carcinoma of the Ampulla of Vater. Of the 21 reported cases he regarded about seven as being above suspicion. "Most of the remainder are either carcinoma of the termination of the common bile duct or of the duodenal surface of the biliary papilla."

In the case under consideration there are several points of interest. In the first place, the patient complained of intense itching for a week previous to the appearance of jaundice. The cause of the itchiness in these cases is not known, but its occurrence in hepatic disorders independently of jaundice seems to show that it is not due to the bile pigment. In Halsted's case of "Primary Carcinoma of the Duodenal Papilla and Diverticulum of Vater"[1] the patient's first symptom was "itching of the skin, which came on suddenly and soon became severe." Next the absence of vomiting, diarrhœa, and pain is deserving of attention. The combination of jaundice with enlargement of the liver and a distended gall-bladder clearly pointed to some obstruction in the common duct. The suddenness of its occurrence seemed to exclude malignant disease and the absence of pain negatived gall-stones, so that I was inclined to regard the case as one of catarrh or swelling of the common duct, though in a case of this sort I should have expected to have found signs of gastro-intestinal derangement, such as vomiting and diarrhœa; moreover, the amount of liver enlargement and the distension of the gall-bladder struck me at the time as being very unusual. The last point to which I wish to direct attention is the temperature. The rapid rise of temperature which occurred on the second day after the patient's admission into the hospital was due, I believe, to the broncho-pneumonic condition. In looking back over the case one can see that the possibility of a new growth within the common duct or in the ampulla should have been considered, but the extreme rarity of the condition led to its being overlooked. The case illustrates the great complexity of the problem to be solved in endeavouring to arrive at the cause in any given case of jaundice.



A, Opening of the right and left hepatic ducts. B, Stomach. C, Opening of Wirsung's duct. D, Growth in the ampulla of Vater. E, Head of the pancreas. F, Duodenum. G, Site of opening of the cystic into the common duct. Opening of the cystic into the common duct = circle three-quarters of an inch in diameter. At the ampulla immediately above growth = one and a half inches.

As regards treatment there is little to be said. The result of operative interference in Halsted's case is not encouraging. Though the immediate result of the operation was good the patient died some 15 months later from recurrence of the carcinoma in the head of the pancreas and duodenum. The lesson taught by this case is the necessity for an early diagnosis so as to ensure the complete removal of the growth.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

POISONING BY IRISH YEW.

BY A. STANLEY BARLING, M.R.C.S. ENG., L.R.C.P. LOND.,

HONORARY SURGEON TO THE ROYAL LANCASTER INFIRMARY; SURGEON TO HIS MAJESTY'S PRISON, LANCASTER CASTLE, AND TO THE LANCASTER POLICE FORCE AND FIRE BRIGADE.

So far as I am able to learn the following is the first case recorded of poisoning by Irish yew. The plant was mistaken for savin and taken by a woman, aged 24 years, who was three months pregnant for the purpose of procuring abortion. The leaves and twigs of the tree were placed in a pan and packed tightly so that the vessel might hold as much as possible. The pan was then filled with water and the whole was boiled for some hours. At the end of that time the pan was about two-thirds full of a black liquid. An ordinary teacupful of this was taken by the woman three times a day. For three or four days nothing unusual was noticed but then the patient began to have what she described as a feeling of pins-and-needles at the pit of the stomach. This got worse and she began to feel ill. At the end of a week nausea and slight griping pains in the abdomen were experienced. On the next day there was some vomiting and the pains were more severe. After a fortnight—during the whole of which time the administration of the decoction was continued in the same doses—the pain was most severe, the vomiting almost incessant, and the patient became unconscious. She remained so for some hours. She was so ill that she was thought to be dying. There was no delirium. After this she refused to take more than one teacupful a day which she continued for a week, not feeling any ill-effects, and then gave it up. Abortion was not induced and six months afterwards she was delivered of a full-term child which had been dead for a short time.

This woman suffered from most of the symptoms of poisoning by the common yew (*Taxus baccata*). Her recovery after taking what appear to be enormous doses may be due either to the vomiting, though this did not occur until she had been taking the stuff for at least a week, or to the possibility that the Irish yew is less poisonous than is its relative.

The poisonous principles of yew do not seem to have been investigated with any thoroughness. We are told that the active principle is an alkaloid named "taxine," but what are its nature, formula, and properties I have failed to discover. It would be most interesting to know also whether this is found in all varieties of yew and in what proportions.

Lancaster.

DIPHTHERIA IN THE NEWLY-BORN.

BY GEORGE A. AUDEN, M.A., M.D. CANTAB.

DIPHTHERITIC infection of the newly-born child appears to be an accident of extreme rarity. Dr. Abraham Jacobi[1] makes an indirect reference to some cases quoted by him in 1880 and these are probably the cases to which Professor William Osler refers in the recent edition of his "Practice of Medicine." Apart from these scant references I have not been able to find any published account of the occurrence. The confirmation of the clinical diagnosis by the result of a bacteriological examination gives additional interest to the following notes.

On the evening of May 12th, 1901, I attended a woman, aged 35 years, in her second confinement, when she was delivered of a full-time healthy child. On May 20th, the eighth day, a greenish, slightly blood-stained, discharge was noticed issuing from the left nostril of the infant in sufficient quantity to stain the pillow. He became fretful and began to take the breast indifferently. On the following morning there was an acrid sanious discharge from both nostrils which soon became excoriated. The child was very fretful and refused food. An attempt to examine the fauces was unsatisfactory and revealed nothing. On the tenth day (May 22nd) there was much nasal discharge, the nostrils being almost occluded. The child breathed with difficulty and with a little inspiratory stertor. There was no recession of the chest walls but the child was somewhat cyanosed and there was great difficulty in getting him to take food. There was a moderate degree of diarrhœa, the pulse was imperceptible, and the temperature was 101° F. Both fauces were seen to be œdematous and upon each tonsil there was a typical patch of membrane. 200 units of antitoxin were at once injected and repeated in four hours and again in the evening, by which time the child's general condition had much improved. The temperature remained at 101°. On the eleventh day (May 23rd) there was less difficulty in breathing but the discharge from the nostrils continued. The temperature varied between 100° and 101°. The child took the breast every two hours. Dr. C. P. White (demonstrator of pathology, Yorkshire College, Leeds) reported on a swab taken on the previous day: "Undoubted diphtheria bacilli in the swab; long forms showing marked segmental staining; streptococci also present." On the twelfth day a slight nasal discharge continued; there was still some exudation on the right tonsil. The bowels were still loose with greenish stools. The temperature was 100°. The child took the breast and slept well. On the thirteenth day the temperature was 98·6°; there was no sign of exudation on the tonsils and the pulse was good. On May 31st the mother's right breast became very inflamed and an abscess appeared to be imminent. The inflammation, however, subsided under treatment. She stated that one month before the child was born she had suffered from a very severe sore-throat which had continued to cause difficulty in swallowing until a week before the confinement. The sanitary arrangements of the house appeared to be satisfactory and no external source of infection could be discovered. There were never any indications of paralytic symptoms and the child is now remarkably robust and healthy.

Although there is no doubt that breast-fed children are less liable than others to contagious or infectious disease, it is difficult to harmonise the facts of the above described case with the theory put forward by Schmid and Pflanz[2] that the maternal milk possesses antitoxic properties. In the present instance the mother fed her child throughout his illness and so far from transmitting any antitoxic elements may herself have been the source from which the infection was derived, for the severe sore-throat from which she suffered immediately before her confinement may not improbably have been due to the specific diphtheria bacillus.

York.

A CASE OF RUPTURE OF DUPUYTREN'S CONTRACTION.

BY T. CRISP ENGLISH, M.R.C.S. ENG., L.R.C.P. LOND.,
HOUSE SURGEON, ST. GEORGE'S HOSPITAL.

IN October, 1900, a man, aged 45 years, was seen at St. George's Hospital with the following history. For 15 years he had suffered from a gradually-increasing contraction of the ring and little fingers of the left hand. There had been no obvious cause to account for this contraction which had put him to great inconvenience; there was, however, a well-marked family history of gout and he had suffered from gout himself. Whilst walking down Piccadilly he had tripped over his stick and fallen heavily on to the kerb, his left hand receiving most of his weight. He heard a "loud snap" and found that his fingers had been forcibly straightened, the skin at the root of the little finger being torn. When seen at the hospital there was a gaping wound at the base of the little finger about three-quarters of an inch long. The tendon of the flexor sublimis digitorum was exposed at the bottom of the wound with its tendon-sheath intact; there was slight hæmorrhage but the digital nerves were apparently uninjured. At the base of the ring finger there were some extravasation of blood and swelling. Both fingers were now quite straight. The wound, which had been contaminated with dirt, was thoroughly scrubbed with 1 in 2000 mercuric biniodide solution and a rough splint of pure tin was moulded to the fingers, the wound healing by granulation. Both fingers were vigorously moved daily, this somewhat retarding the healing of the wound which took place in about four weeks. At the end of this time the patient was discharged, being told that the contraction would return unless the fingers were thoroughly exercised and kept straight. These instructions were conscientiously carried out, and when seen in January, 1902 (15 months after the accident) there was no sign of re-contraction and full movement of both fingers was possible. The slight contraction of the palmar fascia which was noticed before, of course persisted.

Accidental rupture of Dupuytren's contraction is a very rare accident and the above case is interesting as showing that this accident may occur, not only without harm, but even with much benefit to the patient. The most noticeable point in the case is that there was no sign of recurrence of the deformity; the slow progress of the disease, however, may account for this. Mr. W. Anderson, in his Hunterian Lectures on Contractions of the Fingers, related a somewhat similar accident. In this case a contracted finger in Dupuytren's deformity was torn by the handle of a railway carriage and was set free, but the benefit was only temporary. Dupuytren originally practised division of the contracted cords and the superjacent skin in this disease, straightening the finger with a splint. Suppuration unfortunately appears to have been common and "if the patient recovered without the loss of his hand" the process of cicatrisation restored the deformity in a more hopeless and distressing form than ever. This case therefore seems exceptional in that open rupture of the tendon has so far proved curative.

ST. MARY'S HOSPITAL.

THREE CASES OF OPERATION FOR SUSPECTED STONE IN THE KIDNEY, WITH CLINICAL REMARKS.

(Under the care of Mr. EDMUND OWEN.)

THE utility of the Roentgen rays in the diagnosis of renal calculi is very small and we fully agree with Mr. Owen that the employment of this diagnostic means may induce a patient to decline operation though a calculus is present in the kidney. The ordinary uric acid stone gives hardly any image on a sensitive plate but the calcium-oxalate calculus and the phosphatic stone may give definite evidence of their presence. In Cases 1 and 2 renal calculi were found and were removed, but in Case 3 although the signs and symptoms were marked yet no stone was found. An experience like this must have occurred to most surgeons and it is difficult to account for the symptoms, but it is still more difficult to explain why in most cases all the symptoms disappear after such an exploratory operation. Mr. Owen's clinical remarks, which are appended, are of great value.

CASE 1. (From notes by Mr. W. S. Hughes, dresser.)—The patient was a painter's labourer, aged 23 years. The symptoms first occurred in 1894. He complained of sudden stabbing pain in the right loin when he was at his work; the pain, which lasted about two hours, was severe, but was relieved by linseed-meal poultices. Two or three months later the pains recurred and had done so periodically since. He had been treated by medical men who had dieted him and ordered large draughts of barley water. The pain occurred only on movement, especially when there was any jolting, such as during an omnibus ride, and in going up or down a ladder. It was confined to the right loin and was "stabbing" in character. On Feb. 15th, 1902, a severe pain shot from the right loin to the right testis and apparently caused retraction of that organ. He vomited, sweated, and was collapsed; this attack lasted two hours. During the next week he had increased frequency of micturition and he said that his urine was "thick"; one day he passed a small stone by the urethra. He had no blood in his urine during that time, nor had he ever passed blood. The pain in the right loin had, however, persisted since this last attack, and he was admitted to St. Mary's Hospital under the care of Mr. Owen at the end of February, 1902. No abnormal signs, except tenderness and resistance in the right loin, could be made out. The kidney could not be felt. The urine was of specific gravity 1005, had an alkaline reaction, and contained a slight trace of albumin; no blood or pus or tubercle bacilli were discoverable. Mr. Owen cut down upon the right kidney on March 3rd, and a stone was felt in the pelvis of the kidney. A longitudinal incision was made through the outer border of the cortex, and the stone was extracted; it consisted of uric acid. It was of the size of a large filbert, smooth and rounded, and at one end there was a small rough surface from which a portion might have separated.

CASE 2. (From notes by Mr. J. E. Peachell, dresser.)—The patient was a carman, aged 24 years. Four years ago he was suddenly seized with severe pain in the left loin, when sitting in a chair. He had to go to bed; he vomited, and was in great pain till the following morning. For the next two months he had periodical recurrences of the pain which was always confined to the left loin. He had never passed gravel, or had blood in his urine. The attacks usually occurred after jolting, especially when he used the foot-brake of his van. In severe attacks he had usually vomited, and he found that if he lay down when the attack came on the pain soon ceased. He had not had increased frequency of micturition. Linseed poultices had given him more relief than other remedies, but when the attacks occurred as he was driving, he found that bending over to the right side, and supporting the left loin, gave him some ease. On examining, there was nothing to be made out beyond slight tenderness on deep pressure into the left lumbar region. The kidney could not be felt. The urine was of specific gravity 1015; alkaline; and contained a slight trace of albumin, a little pus, and a heavy deposit of urates and phosphates. On March 10th Mr. Owen cut down on the left kidney, and extracted five smooth faceted stones, consisting of uric acid, ranging in size from that of a small, to that of a large, pea.

CASE 3. (From notes by Mr. J. N. Kilner, dresser.)—The patient was a farm labourer from Cornwall, aged 17 years. He began to suffer from attacks of pain and tenderness in the left lumbar region at the end of January, 1902. The pain occurred first when he was sitting down one evening, and left him when he got up and moved about. At the first attack the urine was voided very frequently, but since then there had been no frequency of micturition. The urine had always been abundant, and had never contained albumin or blood. (Report from Dr. F. Chown of Hayle.) On Feb. 5th, 1902, the patient was seized with violent pain to the left of the umbilicus, and this lasted for six days, during which time he had little sleep and required large doses of morphia for relief. After three days of complete ease, the pain came on again and lasted for five days. Since then he had had pain, more or less every day. He was, therefore, sent up to St. Mary's Hospital by Dr. Chown, and he had two or three slight attacks of pain in the first few days after admission. He had no vomiting, rise of temperature, or pain in the testis or groin during the attacks, which had always come on when he had been lying down, and were relieved by his moving about. On examination there were distinct tenderness and resistance in the left lumbar region. The kidney could not be felt. The urine was of specific gravity 1017; acid; and contained no abnormal constituents. The genital organs were normal and there was no tuberculosis in his family. Stone in the kidney was considered to be the most likely cause of the symptoms, there being no other signs of disease of other organs. It was therefore considered advisable to explore the left kidney, and this was done on March 13th, but no stone was found in the kidney nor any morbid condition in that organ or its neighbourhood. It is now a month since the operation, and he has had no further attacks of pain. He is up and about apparently quite well.

Clinical remarks by Mr. OWEN.—Gentlemen, in the course of 10 days we have had before us in this theatre three men in whom we so strongly suspected the existence of renal calculus that we undertook the exploration of the kidney, but in not one of these cases—and this is the interesting point—had there ever been found blood in the urine. Some surgeons, I think, even at the present day would hesitate to operate for a possible stone in the kidney in the absence of the cardinal sign of hæmaturia. But the very proper anxiety of not making a mistake may be carried too far, and it is well to recognise the truth of a remark which was made a few years ago by an illustrious visitor to our country that the man who never makes mistakes never makes anything. After all, it is not a very dreadful thing to make a mistake in the matter of performing "nephro-lithotomy" for a patient with severe renal pain who has no stone, for, strange to say, in not a few cases in which the symptoms of renal calculus have been in classical order and no stone was discoverable on operation, the symptoms entirely disappeared after the negative operation. As to what may be the cause of such a clearing off of the symptoms after the operation I cannot say—any more than one can say how it is that after opening the abdomen for tuberculous peritonitis and then sewing it up again the patient may undergo a prompt and complete recovery. And of this, as you remember, we have had some most remarkable instances lately.

I have already called your attention to the fact that in none of these three cases of supposed renal calculus were the x rays used. And for this reason, that if there be a stone, small in size and composed of uric acid, the x rays may give no sign of it. Then, if the surgeon and the patient have been relying on those marvellous rays for making the diagnosis certain and the indication for operation abundantly clear, the surgeon's judgment may be warped and the patient's courage entirely dissipated by the negative result of the investigation. And quite possibly the patient returns home without a very necessary operation having been undertaken. My practice, therefore, is to ask no help from the x rays when I am proposing to operate in a doubtful case of renal calculus. I do not want them traversing me, as it were, after a blank nephro-lithotomy and saying, "We told you so!" If the rays are to be used generally in doubtful cases the practice will be, I take it, disadvantageous in the long run, for if they are too much relied on they will prevent operation being resorted to in cases when it might have been of great practical value. So the undetected stone is allowed to remain in the kidney to the distress of the individual and the irretrievable damage of one of the most important organs in his body. I repeat, that the negative result of an x-ray search for a suspected renal calculus may be little short of a disaster, and I, for my part, never advise the patient to run the risk of inviting it. It is far better for the patient to take his courage in both hands and let the surgeon explore for the stone in the way which I shall shortly describe.

As regards the importance of the symptom of hæmaturia in the question of stone in the kidney, the first and second of these three cases make it quite clear that it is easily over-estimated. The kidney may be occupied by a large, branching, coral-like stone which may be discovered only at a post-mortem examination, whilst there may have been nothing in the personal history to suggest that there had ever been any renal trouble. That is to say, a large stone may exist in the kidney and give rise neither to bloody urine nor to lumbar pain. It is the small stone which is loose in the pelvis of the kidney or in the cavity which it has hollowed out for itself in the renal tissues, which gives rise to bleeding and neuralgia. Yet in the first and second cases, though the stones were small, there had been no bleeding. In the second case it is evident that the stones were moveable, for their opposed surfaces had been polished by mutual friction, whilst in the first case, as you will remember, when my house surgeon, Mr. Hugh Raven, was feeling for the stone in the kidney, it quickly slipped from its nest into some neighbouring cavity from which we had some slight difficulty in extracting it. I repeat the interesting fact that though in those two cases the stones were not fixed, still there was no bleeding.

The third case proved a real disappointment to me, as I am sure it did to you! How complete the discovery of a stone—however small—would have rendered our little series. You may take it from me that there was no stone present, for Mr. Raven and I searched with such persistence and determination that if there had been one we must have found it; when we started the operation we certainly intended to find one. But I fully expect that the active treatment which the kidney has received will completely and at once free the man from his distressing symptoms. Dr. Chown will, I have no doubt, watch him and report to us further in due course.

Operation.—A few words about the operation. In each case I made an incision from the tip of the last rib transversely inwards over the erector spinæ. In two of the cases the sheath of the erector spinæ was opened. This is a matter of slight importance. What the surgeon particularly wants for this exploration is "elbow-room," and if he makes a niggard incision stopping short of the outer border of the erector spinæ (lest by chance he should open its sheath) he may be thereby hampering himself through the rest of the operation. I called your attention to the fact that one of these men had what the late Dr. Sibson called the "expiratory type of chest." That is to say, the chest was small and the ribs were sloping greatly downwards. In such a man the distance between the tip of the last rib and the border of the erector spinæ must be very slight; and, in order to get more room during the operation, I hooked my fingers under his rib and vigorously pulled it up, and, at the same time, with the fingers of the other hand hooked round the cut edge of the oblique and transverse muscles of the abdomen, I hauled them downwards. Then, as you may remember, the naked, outer border of the quadratus showed itself very conspicuously in the wound; this we pulled inwards, after the manner in which we had dealt with the rib, and so we got a clear access to the posterior surface of the kidney.

In the third case, having felt the kidney all over and squeezed it, fore and aft, between the fingers and thumb, I could find nothing. Then without saying whether I felt a stone or not, I asked Mr. Raven to search, hoping that he might succeed where I had failed. But it was not to be. What was to be done next? Put the kidney to rest and close the wound? No. Explore it all over with a needle? No; I do not believe in that method of searching for a stone. I have known the point of a slender needle springing off some fibrous band in the kidney give by its vibration the suggestion of a stone having been struck when no stone was present. Moreover, it is more than possible that if a small stone were present the needle might just happen to miss it. So I have given up the practice of "needling" the kidney in the search for a stone. What I do now is to complete the enucleation of the kidney and bring it out through the wound, so as to be enabled to make an unimpeded and very complete exploration. This disembedding of the kidney has to be done very gently, of course, and let me tell you that Mr. Jessop of Leeds has recently recorded an instance in which, when undue traction was being made in drawing out a kidney for inspection its pelvis was torn.[1] So the matter of bringing the kidney up on to the surface of the body is to be one of gentleness and coaxing. Then, as in our third case, another methodical exploration is to be made with the fingers and thumb, the ureter also being examined. This failing—as it did fail—the next and the last thing to do is to open the kidney and to explore thoroughly its interior with the finger, and on this question I have special remarks to make.

Opening the kidney.—Some few years ago I had the pleasure of being associated with Dr. B. Rice, of Leamington, in the case of a gentleman in whom he, Dr. Rice, had diagnosed a renal calculus. And, sure enough, when we cut down, there was a stone in the pelvis of the ureter. It was not an easy case: the patient was a hunting man with very muscular loins, and we were hindered by a good deal of bleeding. However, without much difficulty, I removed the stone by making an opening through the posterior part of the fibrous pelvis, and, the bleeding having ceased when we plugged the wound, all went well. But for about a year this gentleman was the subject of a most annoying urinary fistula, which eventually closed spontaneously. After that experience I made up my mind not for the future to attack a stone which happened to be in the pelvis of the kidney by making an opening through the fibrous wall of the pelvis—the expanded ureter, that is. Obviously, there is a greater risk of failure of prompt healing of a wound made through the fibrous tissue of the pelvis of the ureter than through the vascular, glandular substance. At the present time, therefore, I make it my business to arrive at a stone, whether placed in the pelvis or in the substance of the kidney, by making an incision through the renal tissue. This incision need not be made near to the hilum; indeed, it ought not be so placed, because the large branches of the renal vessels are traversing that part in their passage to and from the glandular tissue; but the nearer the vessels approach to the outer border of the kidney the more insignificant do they become. The convex margin of the kidney, therefore, is the part which should be incised for the exploration of the gland for a possible stone, and also for the removal of a stone from the pelvis. And the incision should, of course, be made vertically—in the direction in which the pathologist opens the kidney in the mortuary. I very much doubt if a renal fistula would ever follow on an incision so made into the kidney, but we all know that it is apt so to result from a wound of the ureter or of the pelvis. And the only way of exposing the kidney for making that incision is by "coaxing" the outer border up into the surface wound. When making an incision into the kidney at, or near, the hilum the hæmorrhage may be, often is, indeed, very free; but when the finger has been introduced through the convex border the bleeding is, as a rule, slight, as you have perhaps noticed in these three operations.

ASPATRIA AGRICULTURAL COLLEGE, ASPATRIA (CUMBERLAND).—The annual distribution of prizes gained by successful students at this college was made by Mr. A. Hutcheson of Perth on April 15th. The chairman of the meeting was Sir Wilfrid Lawson, Bart., president of the college. By the kind permission of Sir Wilfrid and Lady Lawson the meeting was held at Brayton Hall.

Medical Societies.

MEDICAL SOCIETY OF LONDON

Clinical Evening Exhibition of Cases

A MEETING of this society was held on April 14th, Dr V H. ALLCHIN, the President, being in the chair

Dr F PARKES WEBER exhibited a case of Infantile Form f Articular Rheumatism with Chronic Enlargement of the pleen, Liver, and Lymphatic Glands The patient, a boy, ged four and three-quarter years, was regarded as a typical xample of an affection which had been well described by Dr G F Still and was usually classed as a variety of rheumatoid arthritis in children. In the present case there was ome apparent enlargement of the knee and elbow joints, but the most marked change was the symmetrical swelling about the articulations of the hands and feet. The swelling, as investigated by the exploring syringe and Roentgen photographs, seemed to be due to infiltration into the periarticular tissues with little, if any, effusion into the synovial cavities. There was considerable limitation of movement in the cervical spinal column and this accounted for the extreme movements of the eyeballs which often gave the face a remarkable appearance. The spleen and liver extended considerably below the ribs and the lymphatic glands in the neck, axillæ, and groin were enlarged, but not greatly so The urine was normal The illness dated from November, 1900, when the boy had an acute disease, said to have been articular rheumatism Before this he could walk and was apparently healthy Occasionally there had been moderate fever and about the beginning of November, 1901, there was a definite attack of endocarditis and the heart, which previously had appeared to be healthy or only very slightly dilated, showed signs of disease of the mitral valve. It was this attack of endocarditis and the fact of pericardial adhesions having been found in other cases which made Dr Parkes Weber think that the affection was more allied to articular rheumatism than to any forms of rheumatoid arthritis in adults. Cases like the present might perhaps be regarded as due to the same specific microbic infection as Dr F J Poynton and Dr A Paine had shown to exist in acute and subacute rheumatism, the clinical differences being explained as modifications resulting from the age of the patients In the same way tuberculosis in young children was clinically generally very different from tuberculosis in adults.—Dr A. E SANSOM could only regard the case either as one of rheumatism plus something else or as not being rheumatism at all He did not regard the arthritis as one of rheumatic origin the characters of which were a relatively painless effusion into the joints of a few weeks' duration The cardiac lesion in this case was very slight in his opinion, if, indeed, any existed. The cases described by Dr Still were in no way connected with rheumatism in his (Dr Sansom's) belief —Dr EDMUND CAUTLEY agreed with the previous speaker that the condition before them was not rheumatic in origin but was rather one of osteo-arthritis associated with rickets —Dr H. D ROLLESTON also regarded the cases as rachitic associated with joint mischief The latter was probably a septic condition and the heart was, in his opinion, clearly affected.—Dr A. MORISON did not agree as to the existence of organic heart disease The case was arthritidis supervening in a rachitic subject.—Dr POYNTON had, with Dr Paine, investigated this case bacteriologically but had not found the characteristic microbe of acute rheumatism He referred to two cases which threw some light on the subject and which tended to show that rheumatism might occur in a malignant and non-malignant form.—Dr PAINE referred to the two forms of joint mischief met with in rheumatism and mentioned some data elucidating the infective origin in these cases.—The PRESIDENT deprecated the use of the word "rheumatic" in these cases. He thought it was incorrect to assume that the age of the patient would modify a common disease like acute rheumatism to the extent met with in this boy —Dr PARKES WEBER, in replying remarked that recent investigations tended to show that there was but one rheumatic poison, though the cases might differ clinically No doubt this child was rachitic, but he adhered to the idea of the rheumatic origin of the case before the society

Dr WILLIAM EWART exhibited a female patient, aged 32 years, the subject of Chronic Nephritis, who had derived marked benefit from the treatment by drainage and feeding which he had advocated in 1898 The incisions at the ankles had drained continuously for four and a half months, enabling the patient during that time to take with conspicuous advantage abundant and various supplies of food. Since the spontaneous healing of the incisions early in January, 1902, she had enjoyed the same liberal dietary without any return of the sub-uræmic symptoms such as had previously been occasioned by a mixed diet. Under the influence of iron, mercury, and arsenic, which she was now taking, she was feeling strong and well, but the albuminuria persisted (about 0·4 per cent.) and there was still some slight œdema of the legs —The PRESIDENT asked whether the treatment advocated had great advantages over frequent sweatings, which might, perhaps, be equally efficacious —Dr SANSOM assumed that the case was one of chronic parenchymatous nephritis and referred to a case in which after incisions into the legs these were put into a warm foot-bath every day for many days The water of the bath became extremely ammoniacal. The uræmic symptoms improved but the patient died

Dr BERTRAND DAWSON exhibited a case of Syphilitic Fibrosis of the Lung occurring in a woman aged 50 years. The onset of the illness was gradual, beginning nine years before with a hacking cough which did not however, at first affect her health. When Dr Dawson saw the patient for the first time, six years ago, the symptoms were sweating cough, spitting, and slight hæmoptysis. There was slight and irregular fever and the fingers were clubbed. The physical signs were confined to the right chest and these could have been regarded as an active supervening on a chronic phthisis, with signs of cavitation the latter most marked at the posterior base. The left lung was free. This case, however, was without doubt one of non tuberculous fibrosis of the lung with some secondary bronchiectasis There was a natural hesitancy to diagnose syphilis of the lung on account of its rarity and the difficulty of excluding othe causes of pulmonary fibrosis. The facts in this case were however, strongly in favour of syphilis because, first the acute symptoms and signs in the chest ameliorated unde iodide of potassium, secondly, the symptoms and sign especially characteristic of fibrosis came on subsequently t the anti syphilitic treatment—that is, as the result of the healing of some active process, thirdly, that active proces was not tubercle though its manifestations in part resembled those of tubercle (there was no history of pneumonia which often explained unilateral fibrosis), and, fourthly, there were evidences of tertiary syphilis antecedent to the chest mischief and there were definite signs of syphilis concurrently with the active lung trouble and healing simultaneously with it.—Dr A. F VOELCKER agreed with the diagnosis of syphilitic fibrosis and bronchiectasis of the lung Possibly there had been a gumma around the bronchus and the fibrosis had arisen by causing obstruction He referred to a case by way of illustration.—Dr ROLLESTON remarked that the increase of the secretion from the lung might be due to the administration of iodide. When this drug was given in lung disease, especially with stenosis of the bronchi, it should be guarded by belladonna.

Dr DAWSON also exhibited a case of Aortic Incompetency with well marked Diastolic Thrill and one of Phthisis in conjunction with Albuminuria and Paralysis of the Sixth and Seventh Cranial Nerves on the left side.

Dr STCLAIR THOMSON and Mr ALBERT CARLESS exhibited a case of Epithelioma of the Epiglottis and Base of the Tongue treated by Transhyoid Pharyngotomy The patient, a man, aged 60 years had complained for eight or nine months of a lump at the back of his throat which had gradually increased in size but did not cause much pain or inconvenience. There was a large indurated ulcer with raised everted edges extending over the epiglottis from near its base and encroaching upon the back of the tongue for nearly an inch. An enlarged and indurated gland could be felt beneath the angle of the left side of the jaw On Sept. 4th the first operation of transhyoid pharyngotomy was performed after a preliminary tracheotomy The growth was exposed and was removed by the scissors The wound was partially closed and the tracheotomy tube retained The patient subsequently did very well. The second operation for removal of glands was performed on Oct. 11th. The patient had remained perfectly well since that date and there was now (18 months since the first operation) no sign of recurrence.

Dr. ROLLESTON showed a man, a French-polisher, aged 40 years, with Pigmentation, probably analogous to a blue line, of the Inner Surface of the Lower Lip. The teeth on contact with the lower lip were very foul and the gums showed a "blue line." There was no pigmentation on the palate and no reason to think that he had Addison's disease. It was thought that the blue line was due to lead absorbed in beer taken early in the morning.—Dr. VOELCKER did not regard the pigmentation on the lip as due to lead but only as a superficial staining due to contact with the abundant foul tartar on the lower front incisors.—Dr. M. E. LING recalled a case of lead-poisoning produced by the "tinfoil" in which packets of cocoa were packed.

Dr. STCLAIR THOMSON exhibited a case of Ulceration of the Ala Nasi, probably of syphilitic origin.

PATHOLOGICAL SOCIETY OF LONDON.

Tuberculosis in Sheep.—The Recognition of Tetanus by Extracting the Toxin from the Viscera after Death.—The Bacteriology of the Veldt Sore.

A MEETING of the Bacteriological Section of this society was held on April 15th, Dr. F. W. ANDREWES being in the chair.

Mr. ALEXANDER G. R. FOULERTON read a paper on a case of Tuberculosis in a Sheep. The specimens were obtained from a carcass which had been seized by Dr. George Newman, the medical officer of health of Finsbury. The carcass was much emaciated and there were extensive tuberculous lesions in the lungs, spleen, liver, and kidneys, and in the lumbar, dorsal, sternal, anterior mediastinal, mesenteric, and cervical glands. These lesions showed various stages of degeneration and calcification. No acid-fast bacilli could be demonstrated on microscopic examination. The inoculation of guinea-pigs, however, showed the nature of the case. Two animals inoculated died respectively 28 and 35 days after infection with a typical tuberculosis. Tuberculosis of sheep was extremely rare, a case published by Professor John McFadyean of the Royal Veterinary College in 1900 having been apparently the first case of the sort published in this country in which complete bacteriological proof of the infection had been given. This case showed that the sheep was susceptible to a natural infection in a high degree and infection could be experimentally conveyed by feeding or inoculation. The freedom which sheep enjoyed from tuberculosis was to be explained by their open-air habit of life. The factor which determined the freedom from tuberculosis amongst, for instance, Highland cattle as compared with the excessive prevalence of the disease amongst dairy cattle who were housed in confined, ill-ventilated byres was no doubt the difference of their environment.—Dr. ANDREWES remarked on the prevalence of tuberculosis among animals which led an indoor life. Cows which were kept shut up in sheds suffered more than bullocks which led an outdoor life. This would explain the relative immunity of sheep.—Mr. G. H. SHATTOCK agreed with Mr. Foulerton's views and said that when the suggestion was originally made that sheep were normally immune to tubercle he had attempted to cure tuberculous guinea-pigs by the injection of sheep's serum, but needless to say this was not successful.

Mr. H. J. WARING described a new method of Extraction of the Toxin of Tetanus from the Liver and other Solid Viscera of the Human Body. The details of the method were as follows. As soon as possible after death the viscera which were intended for investigation were removed from the body and as much blood as possible was squeezed out of them by pressure. The material was then minced into small pieces. It was then weighed and mixed with an equal quantity of pure glycerine in a closely-stoppered glass jar. The process of mincing and mixing should be carried out in a dark room or away from direct sunlight, since this soon caused the toxin to become inert. The jar was then placed in a cool dark cupboard and left there for three or four days, the jar being occasionally shaken. At the end of several days the mixture was filtered through glass wool so as to separate the glycerine and the substances soluble in it from the solid and insoluble débris. Details were given of a series of experiments on mice in which varying amounts of the glycerine extracts were injected into the tissues. These in most cases were followed by the development of symptoms which appeared to be those of mouse tetanus. Five cases of acute traumatic tetanus which terminated fatally in St. Bartholomew's Hospital provided the material for these investigations. He drew attention to the difference of the time of appearance of ordinary mouse tetanus and that induced by large doses of the glycerine extracts and explained the absence of the incubation period in these cases by suggesting that the toxin in the liver was probably in the form of a toxinogen. He also drew attention to the possible application of this method of investigation to the establishment after death of a correct diagnosis in those cases of patients who had presented indefinite symptoms of tetanus and in whom a bacteriological diagnosis had not been possible or had been negative.

Dr. ANDREWES also described experiments in which he had employed the method of Glycerine Extraction of the Spleen in cases of Doubtful Tetanus as a means of Diagnosis after Death. His results confirmed those of Mr. Waring. In the course of the past year he had met with two cases in which, during life, tetanus had been suspected but was not clearly present. In one of these the bile and the glycerine extract had failed to produce tetanus in animals and the post-mortem examination had revealed tuberculous caries of the dorsal spine which seemed fully capable of explaining the spasms observed during life. In the second case, which was that of a girl who developed trismus and other nervous symptoms 18 days after vaccination and who died from broncho-pneumonia, tetanus had been strongly suspected, and this was confirmed by the results of experiment. A glycerine extract of the spleen produced characteristic tetanus in mice, while in a mouse which received some antitetanic serum with the spleen extract the symptoms were much delayed and profoundly modified, although a fatal issue was not averted. Dr. Andrewes was of opinion that this method was likely to prove of great value in the diagnosis of tetanus after death. There could be no doubt in the minds of those who saw the experiments that the symptoms produced by the glycerine extract were truly those of tetanus, though they presented the novel feature of an absence of the incubation period invariably seen after the administration of tetanus toxin derived from cultures of the tetanus bacillus. The most reasonable explanation of this seemed to lie in the supposition that the filtered culture of tetanus bacilli contained a precursor of the toxin—a "toxinogen"—rather than the fully-formed toxin, whereas the glycerine extract from the viscera contained the fully-formed toxin, and its injection into mice was therefore unattended by any incubation period.—Dr. GEORGE DEAN pointed out that it was necessary before coming to the conclusions at which Mr. Waring and Dr. Andrewes had arrived to make certain that none of the substances employed were capable of giving rise to symptoms liable to be mistaken for tetanus. It had been well known for a very long time that it was possible to extract tetanus toxin from the blood or viscera of persons dying from the disease. But some observers had already described a "strychnine-like" substance extracted from dead bodies which could produce tetanus in mice without a latent period, though the results even in their own hands had been inconstant. Other observers had obtained tetanising substances from animals which had not suffered from tetanus. Moreover, there were other substances which, when injected into mice, could produce tetanic symptoms. He (Dr. Dean) had produced them by injecting one-third of a cubic centimetre of simple glycerine and the mice died. Very minute doses of ammonium sulphide and (as Blumenthal had shown and he, Dr. Dean, had confirmed) from one-quarter to one-half of a cubic centimetre of a concentrated solution of common salt were capable of producing in mice symptoms which were absolutely indistinguishable from those of tetanus. Great care was necessary before coming to the conclusion suggested by Mr. Waring and Dr. Andrewes.—Dr. W. BULLOCH agreed with the previous speaker and remarked that if the antitetanic serum referred to really neutralised the poison observed by Mr. Waring it ought to have done so in doses much less than 0·5 cubic centimetre.—Mr. WARING, in reply, said that as regards the glycerine extracts he had made several control experiments with glycerine alone but had never succeeded in producing tetanus in mice.

Mr. N. BISHOP HARMAN made a further communication on the Clinical and Pathological Characters of the Veldt Sore Prevalent amongst the Troops in South Africa. This skin lesion was found to affect on an average 20 per cent. of the combatants engaged in the war. Clinically it arose as a blister, beside some abrasion of the epidermis, it exuded a serous fluid, did not cause either marked damage to the dermis, lymphatic infection, serious pain, or constitutional symptoms. Microscopic sections of the sore showed the organism penetrating the stratum lucidum in advance of the blister formation. Evidence went to prove that the sore was of a scorbutic nature, being difficult of treatment in the field, but yielding without treatment on return to camp or town. There was no permanent cicatrix or deformity. The organism in the blister fluid was a coccus 0·8 μ in diameter, arranged in pairs, with signs of capsulation, staining with aniline dyes and by Gram's method. In culture it grew readily, producing yellow colonies of cocci in masses and an acid reaction. It was very resistant of destruction, it would survive drying for 61 days, dry heat at 110° C for five minutes, moist heat at 86° C for five minutes, and mixing with excess of 1 in 1000 solution of $HgCl_2$ for 40 minutes He produced the lesion by inoculation of the blister fluid on himself and again to a lesser extent from the inoculation of remote subcultures (10 and 14) Inoculation on animals produced no particular features. By reason of the distinctive features of the lesion, the appearance of the organism in the blister, the luxuriance of the growths, and the great resistance to destruction exhibited by the organism, it might be considered to differ from the staphylococcus pyogenes aureus and be distinguished as the "micrococcus vesicans."—Dr. BULLOCH thought it unwise to draw conclusions based on the resistance of an organism to antiseptics; staphylococcus aureus would resist 1 in 1000 mercuric chloride up to 20 minutes. The features and effects produced by staphylococcus aureus depended very much on its sources and the soil on which it was grown, and there did not seem to him any essential differences between this ubiquitous organism and that described by Mr. Harman.—Mr FOULERTON regarded it as doubtful, but on the whole he thought that there were *essential differences between the two organisms.*—Mr. GEORGE PERNET remarked that impetigo contagiosa *assumed many different forms under varying conditions.* Might not the "veldt sore" be an aberrant form of this disease? The clinical features of the sore described by Mr. Harman appeared to him (Mr. Pernet) to resemble very closely those of impetigo contagiosa bullosa, as met with in the East.—Mr. HARMAN, in reply, said that he had used many different strains of the staphylococcus aureus in his control experiments. The veldt sore microbe was always a diplococcus.

CLINICAL SOCIETY OF LONDON.

Cases Illustrating the Mode of Origin of Certain Cysts of the Neck.—Intestinal Obstruction due to Embolism of a Branch of the Superior Mesenteric Artery.—Cerebellar Abscess with Sudden Paralysis of the Respiratory Centres.—Simulation of Acute Peritonitis by Pleuro-pneumonic Disease.

A MEETING of this society was held on April 11th, Mr. HOWARD MARSH, the President, being in the chair.

Mr. THOMAS CARWARDINE (Bristol) read a paper on Cases Illustrating the Mode of Origin of Certain Cysts of the Neck. Cysts and fistulæ arising from the thyro-glossal duct, he observed, usually had a pedicle which passed through the thyro-hyoid membrane in the middle line below the hyoid bone, between it and the thyroid cartilage. These, he suggested, might be termed *thyro-hyoid* cysts. He related the case of a man, aged 31 years, deaf and dumb and one of twins, with a fluctuating, superficial median tumour of the neck, overlapping the episternal notch and manubrium sterni, and a hard cord could be traced upwards from it in front of the cricoid cartilage. The pedicle was found to pass through an interval in the cervical fascia into the middle of the crico-thyroid membrane. It was evidently what he would call a *crico-thyroid* cyst. Two years later he met with a similar and homologous cyst in the space between the lower jaw and the hyoid bone in a lad, aged 12 years, who had noticed a lump in his throat for six months. The diagnosis of *hyo-mandibular* cyst proved to be correct at the operation. There were thus three median cysts—hyo-mandibular, associated with the first branchial or visceral cleft; thyro-hyoid, associated with the second cleft; and crico-thyroid, with the third cleft. He related a case of cystic hygroma in a baby a few weeks old in which the cyst, like a ranula, projected under the tongue. He described the anatomical relations of the cyst, observing that the cyst appeared to have originated in a lateral diverticulum of the first, or hyo-mandibular, cleft. He next referred to a tumour below the left angle of the lower jaw in a young man which proved to be a chondro-adenoma; also to a case of dermoid cyst of the whole of the first branchial cleft. His last case was that of a man, aged 33 years, who had had a swelling on the right side of the throat for two years which he thought had arisen from a diverticulum of the sinus pyriformis—i.e., from the third or fourth branchial cleft. He discussed the classification of these cysts according to their origin, into median and lateral, corresponding to the visceral clefts, and alternating with the visceral arches.—Mr A. A. BOWLBY remarked that the relation of these cysts to the branchial clefts could not well be refuted. Those in the thyro-hyoid space were the most troublesome to deal with because part of the cyst generally arose behind the hyoid bone, and he mentioned a case in illustration which resulted in a fistula of five years' duration in spite of treatment. Epitheliomatous or malignant cysts should, he thought, be included among the lateral cysts.—Mr. STANLEY BOYD remarked on the difficulty of curing these cysts and referred to a case of median cyst resulting in fistula which only healed after three or four operations. The tract of this cyst went behind, not in front, of the hyoid bone.—Mr. A. E. BARKER asked whether cystic hygromata were not really of lymphatic origin. Some of those which he had operated upon were practically lymphatic nævi.—Dr. STCLAIR THOMSON asked if any of the speakers had tried the efficacy of dividing the hyoid bone as originally suggested by Mr. Arthur Durham.—Mr. CARWARDINE, in reply, agreed as to the difficulty of curing the fistulæ resulting from these cases. Epitheliomatous cysts should certainly be classed with those arising from the branchial clefts. Some hygromata arose from these clefts, others were of lymphatic origin. Mr Boyd's case suggested a hyo-mandibular origin. The suggestion *of dividing the hyoid bone seemed to him to be a very* good one.

*Dr W. J. TYSON and Mr. W. W. LININGTON communi*cated a paper on a case of Intestinal Obstruction due to Embolism of a Branch of the Superior Mesenteric Artery. The patient was a woman, aged 66 years; she complained of slight pain over the liver, sickness, constipation, and some epigastric tenderness, her temperature being normal. The symptoms gradually became worse and ultimately the vomit became "coffee-ground." Laparotomy was done and the small intestine was found to be slightly congested and adherent in the right fossa, where about a foot of gangrenous bowel, greatly thickened, was seen. The affected part, which was obviously due to thrombosis, was freely excised and the end united with a Murphy's button. She died 36 hours after the operation and post mortem atheromatous erosion of the descending aorta was found, with blocking of a branch of the superior mesenteric artery. Mounted specimens from the case were exhibited. Dr Tyson then discussed the symptomatology of this condition, remarking that the symptoms were at first those of ordinary colic with a gradual change in the vomit. Constipation was the rule, but diarrhœa was often present, and later tympanites. The prognosis was always grave but not absolutely fatal.—Mr. J. R. LUNN referred to a case of Intestinal Obstruction due to Embolism of the Superior Mesenteric Artery consequent on compression applied on the distal side of an abdominal aneurysm of the abdominal aorta which arose at the root of the superior mesenteric artery. The symptoms were those of intestinal obstruction, small rapid pulse, and rapid breathing. Death was due to gangrene of the intestine *caused by arteri*al thrombosis.—Mr. H. L. BARNARD referred to a case which at the time of the operation was thought to be embolism of the superior mesenteric artery, but at the necropsy acute thrombosis of the portal vein was found. There was acute gangrene of the whole of the small intestine. Total constipation was present in this case.—The PRESIDENT referred to the case of a man who whilst hunting fell in a prone position on a heap of stones. He was conveyed home but felt no ill-effects for 48 hours and even went to business. Sudden collapse supervened and the same evening an operation was performed and a piece of gangrenous intestine, four feet long, was found. The patient died and the superior mesenteric artery was blocked by an embolism which appeared to have arisen by the stretching of the artery.—Mr. BOWLBY referred to the case of a man who was admitted to St. Bartholomew's Hospital for gangrene of the finger supposed to be due to frost-bite. Shortly afterwards he was seized with abdominal pain, collapse, and vomiting, and died in 18 hours. At the necropsy an ante-mortem clot was found in the left side of the heart and emboli from this had blocked the arteries of the digits and the superior mesenteric artery.—Dr. E. P. PATON referred to the case of a woman, aged 25 years, which resembled that mentioned by Mr. Barnard, in which no reason for the thrombosis could be discovered.—In reply to the PRESIDENT Dr. PATON said that the patient presented no evidences of gout.—Dr. TYSON, in replying, said that a large number of these cases had hæmorrhage from the bowel which was a feature of diagnostic value.

Mr. BARKER communicated a case of Cerebellar Abscess with Sudden Paralysis of the Respiratory Centre occurring in a girl, aged 14 years, who, three months before admission, had had scarlet fever with otitis media. A fortnight before admission she complained of ear-ache followed by great weakness and vomiting and rigors. The limbs were flexed and the head was retracted and there was dulness of intellect. Intracranial abscess with thrombosis of the lateral sinus and deep jugular vein was diagnosed, and it was decided to operate, but when the patient was lifted to be taken into the theatre respiration ceased, and in spite of artificial respiration and the inhalation of oxygen there was no sign of normal respiration though the heart continued to beat strongly. Artificial respiration was kept up for an hour, when, as normal respiration did not return, he made a small incision through the skull into the temporo-sphenoidal lobe. No pus was found, but on passing the needle into the lateral ventricle a large quantity of almost clear fluid was evacuated. He then opened the skull over the lateral surface of the cerebellum and reached foul gas and pus anteriorly. This, however, had no effect on the respiration or heart. Artificial respiration was kept up for another hour, but the patient was obviously dead, though the heart continued to beat as before for two hours and 35 minutes after natural breathing had ceased. Post mortem, a large cerebellar abscess was found in the usual situation.—Sir DYCE DUCKWORTH referred to a series of such cases which he communicated to the International Medical Congress at the meeting in Moscow. They all illustrated the fact that in these cases of cerebellar abscess the fatal process took effect first on the respiratory centre and then, some time later, on the cardiac centre. The inference was that the respiratory centre was more vulnerable than the cardiac centre. It was a curious phenomenon to observe when a patient absolutely stopped breathing although the heart continued beating.—Mr. BARKER, in reply, said that the reason why operation was not done earlier was because he was not certain of the diagnosis.

Mr. BARNARD read a paper on the Simulation of Acute Peritonitis by Pleuro-pneumonic Diseases. Modern writers for the most part did not include peritonitis in the differential diagnosis of pleurisy or *vice versâ*. The thoracic conditions which had given rise to these abdominal signs in Mr. Barnard's cases were—pleuro-pneumonia, three cases; pyo-pneumothorax apparently originating in the apex of the lower lobe, two cases; and traumatic pleurisy with fracture of the left lower ribs, one case. The abdominal signs and symptoms which resulted might be divided conveniently into parietal and visceral. The abdominal wall was acutely tender and painful. The muscles were in spasm so that the abdomen felt hard. The deepest anæsthesia was necessary to relax this spasm. Respiration was of the costal type. The patient frequently suffered from nausea, hiccough, and vomiting which might be urgent and bilious. In some cases the onset was sudden with collapse like perforative peritonitis. The diagnosis, however, was easy if once suspicion was aroused. The chief points were the rapid respiration (40 and upwards), the slow good pulse (under 100), and the fact that the abdominal wall softened momentarily at each inspiration. Direct signs of the thoracic condition were often wanting for 24 hours. The pathology was one of "referred pain" and divided itself into three heads: 1. Irritation in continuity of the lower six dorsal nerves would explain abdominal hyperæsthesia and spasm. 2. Referred visceral pain would explain the abdominal and head pain of an early broncho-pneumonia, phthisis or bronchitis not involving the pleura. Visceral impulses passed into the root ganglia of the seventh, eighth, and ninth dorsal nerves and exalted their excitability so that impulses from the skin to those ganglia became painful. Reflex spasm followed in the distribution of the nerves. 3. The visceral signs must be explained either by some reversal of this reflex or by direct involvement of the splanchnic nerves (from the sixth to the twelfth dorsal nerves) in or above the diaphragm.—Sir DYCE DUCKWORTH complimented Mr. Barnard upon his paper and remarked that it led irresistibly to two conclusions—viz., firstly, that medical cases such as supposed intestinal obstruction or peritonitis should be admitted to medical wards, and secondly that a thorough investigation of such cases by those accustomed to estimate the value of the symptoms of visceral disorders would in all probability obviate errors in diagnosis.—Dr. J. A. HAYWARD referred to a case exactly the reverse of those recorded where symptoms due to acute peritonitis simulated those of pneumonia. The patient presented all the typical signs of pneumonia with a well-marked pleural rub, but these eventually proved to be at the necropsy due to rupture of the appendix and acute purulent peritonitis. The lungs and pleura were perfectly healthy, excepting for the presence of two ounces of fluid in the latter.

HARVEIAN SOCIETY OF LONDON.

Functional Vaso-motor Disturbances.

A MEETING of this society was held on April 10th, Dr. ROBERT MAGUIRE, Past-President, being in the chair.

Dr. R. L. BOWLES read a paper on the Practical Treatment of Functional Vaso-motor Disturbances. After referring shortly to the physiological, anatomical, and experimental evidence of vaso-motor action Dr. Bowles gave, as examples of functional disturbance, the dilatation of the large vessels after severe exertion, the pulsating dilatation of the abdominal aorta in neurotic women, and pulsating dilatation of the carotids in the anæmic and of the temporal arteries in headache and neuralgia. He pointed out that the venous system and the heart were liable to similar partial and temporary fluctuations. Vague pains and loss of power in the lower limbs, so often ascribed to sciatica, were shown in some instances to be due to functional disturbances of the blood-supply. Other functional disturbances, such as blushing and pallor, the symptoms often present at the "change of life," the effects of vaso-motor action on the central nervous system, the vaso-motor symptoms in exophthalmic goitre and myxœdema, and intestinal phenomena due to similar causes were also referred to. In some cases Dr. Bowles thought that the symptoms were due to toxins acting through the nervous system and in others that they were due to derangement of function arising from fatigue. Many other vaso-motor effects were lightly touched upon, such as chilblains, "dead fingers," and Raynaud's disease. For treatment Dr. Bowles insisted upon the importance of heat, light, electricity, massage, baths, change of scene and surroundings, and so forth. He did not bring forward any wonderful novelty or so-called specific, but, as the result of a great many years' trial and experience, he strongly recommended the persistent use of valerianate of zinc in doses of one grain three times a day. In neurasthenia he had had most beneficial results from the effects of valerianates, and he quoted an instance of nerve deafness in a woman who had been stone deaf for eight years and who had been told that there was no hope of recovery. After two and a half years of the persistent administration of the valerianate of zinc the patient completely recovered her hearing. He had also found the drug of great use in the treatment of tinnitus aurium and in many other nervous conditions; so much so, that he had come to rely upon the drug very largely in all cases of the neurasthenic type.

Dr. ALEXANDER MORISON said that Dr. Bowles appeared to have seen a good number of specimens of local vascular change in the carotid, the subclavian, and the veins of the lower extremities. Some of those conditions might be described as intermittent claudication, a subject which had been vigorously worked at by some French physicians and applied largely to certain visceral disturbances which were regarded by some as of vaso-motor origin, but without acknowledging the fact that the idea was due to Burns of Glasgow, 70 or 80 years ago, whose work would now repay careful perusal, as it was the origin of several twentieth-century theories. He agreed with Dr. Bowles's judicious remarks in distinguishing cases of claudication from those of neurasthenic origin. He was glad to hear of such good results from valerianate of zinc, as he himself was somewhat sceptical of its therapeutic value. But in the case of a drug taken persistently for two years, as mentioned by Dr Bowles, the factor of time and the altered circumstances and conditions possible must not be lost sight of

Dr PARKES WEBER said that the question of contraction of vessels was a most important one, as such contraction could produce an immense effect It had been proved practically by microscopical examination that veins could so contract that the lumen was almost obliterated. He had had the opportunity of examining gangrene of the extremity in which examination afterwards showed no very considerable organic disease and the conclusion almost necessarily arrived at was that the obstruction was above the part examined If the blood was not circulating properly in the foot or hand there was evidently plenty of blood there, and as there was no sign of arteries being contracted the suggestion was that the small veins were contracted. In some typical cases of Raynaud's disease only the small arteries were contracted In Dr Bowles's case, in which an enema was vomited some time afterwards, evidently there was some disturbance of peristalsis analogous to what happened in the circulatory system He once saw a case in which an enema coloured with methylene blue was vomited 10 minutes afterwards. This was done repeatedly and he thought that there must be in such a case an anti-peristalsis

Dr. CAUTLEY said that most of the cases mentioned by Dr. Bowles in his paper seemed to be beyond the first half of life, but he (Dr. Cautley) had been inclined to regard vaso-motor disturbances as more common in the earlier periods of life and more so in females than in males He asked what was Dr. Bowles's experience in the matter of age in cases of local dilatation of arteries and what was the prognosis apart from the results for the time being Was there any tendency to atheroma or aneurysm later? He was sceptical about the value of a drug which required to be persisted in before any definite results accrued But such a case as that quoted showed that treatment was of benefit, because the patient was of that age at which her deafness would tend to increase rather than to disappear

Dr MAGUIRE regarded some of the cases quoted as having an organic basis—i.e., organic blocking of vessels. It was difficult to be definite on such a subject as vaso-motor disturbance. But one knew that a person who came with blue-red hands, freely perspiring, was slack, and if the skin of such persons were pressed upon the colour would return very slowly. It was not very satisfactory to make the test on the hands because much depended on the extent of exposure, but valuable indications could be obtained on the skin of the chest. He drew attention to disorders of the cerebrum due to vaso-motor disturbance. Those who had seen many cases of general paralysis of the insane would appreciate that a case might show itself not by melancholia or grandiose ideas but by sudden aphasia for a moment or two He had not seen much benefit result from valerianate of zinc, although he had generally given it in larger doses than had Dr Bowles. Two drugs of great value were musk and castoreum. The first was too expensive to be within the reach of ordinary patients, but in doses of five grains three times a day its effect was very good. Castoreum was obtained from the preputial glands of the beaver, musk coming from the same glands of the musk ox. Castoreum should be given in from 10 to 20 minim doses with an alkali It was unpalatable and bad smelling but was very useful

Dr BOWLES replied.

OTOLOGICAL SOCIETY OF THE UNITED KINGDOM.

Discussion on an Examination of the Ears of 1000 School Children.

A MEETING of this society was held on April 14th, Dr URBAN PRITCHARD, the President, being in the chair

A report by Mr ARTHUR H CHEATLE upon the Examination of the Ears of 1000 School Children was presented and discussed. Mr. Cheatle, in opening the discussion, said that the objects which he had in view in undertaking the investigation were twofold—first, to ascertain the amount of ear disease in the children of the poorest class; and secondly, to draw attention, if necessary, to the subject in the hope that steps would be taken to deal with it. The classification of the lesions met with presented difficulties which were very great and he had no doubt that criticism might justly be directed against the one adopted, and also, perhaps, against the method of examination. For instance, objection might be taken to the use of the term "normal" which was used in the report to mean that the membranes appeared normal, and that the hearing was sufficient to pass the whispered voice test at a distance of 18 feet. The fallacies of this test were alluded to in the report, but in the circumstances it was the only one possible in the great majority of cases and it was of the greatest value in picking out children with diminished hearing For purposes of comparison it would be of great interest, he said, if an investigation could be conducted amongst children of the better classes who lived under better conditions. The schools at Hanwell, however, were practically perfect from a hygienic point of view and the lives of the children were essentially healthy He regretted that he had not been able to classify those who had lived almost all their lives in the institution from those who had come as temporary *lodgers* *Inability to pass the test with one or both ears* was present in 520 out of the 1000 children Many of these, especially in the group of depressed membrane associated with adenoids, had not been noticed by their teachers to be deaf, the deficiency only being detected upon examination. This point was of the utmost importance, for if children so affected were to be saved from deafness in later life childhood was the time for treatment. It amounted to this, that unless children were systematically examined any deficiency in hearing would pass unnoticed and untreated until it became so great as to interfere with the future work of their lives and then perhaps treatment would be of little avail Mr Cheatle considered that all children, whatever their station in life, should at some period be thoroughly examined, the period that would be best for the purpose would be open to discussion, but he suggested the age at which they should be able to give intelligent and trustworthy answers to simple tests, unless anything amiss in the hearing had been noticed earlier Passing to further details in the report he said that the comparatively large number of foreign bodies in the ears was noteworthy, 12 of the 18 cases occurred in girls The children were all unconscious of their presence Mr. Cheatle said that he was not positive whether congenital perforation in Shrapnell's membrane did occur; the eight instances recorded suggested that it did The association of depressed membranes with deafness and adenoids was well marked. Out of 166 cases, in 141 there were adenoids Of the cases classified as sclerosis deafness was present in all, the membrane appeared to be normal and slight improvement resulted from inflation. They all occurred in girls. It was little less than appalling to realise that 335 of the 1000 children examined were, or had been, the subjects of discharge from one or both ears, 88 of these might be spoken of as walking on the edge of a precipice and six as being at least half over Of the 88 cases in which suppuration was present in 71 there were adenoids and in 13 there was granulation tissue in the ear The number who had previously suffered from chronic middle-ear discharge was 247, of these 171 had adenoids and a dry perforation was present in 57 It appeared from the statistics that the left ear was less liable to infection than the right, for out of the combined past and present suppurative cases, numbering 335, both ears were affected in 126, the right in 127, and the left in 82 The association of adenoids with ear disease was most marked, they were present in 434 children, of whom 394 presented some aural troubles. Mr Cheatle finally raised the question as to what steps should be taken in the matter by the authorities. To his mind it was a matter that they could not afford to neglect, it was of no use to leave it in the hands of the parents, for many cases of commencing deafness could only be detected on careful examination and, moreover, childhood was the time for treatment. He recommended that the systems employed in Germany, Switzerland, and Sweden should be investigated and reported upon The one now in force in Germany would probably be the most applicable, as it dealt with a large population. He had heard from Dr Arthur Hartmann of Berlin that in the majority of the large cities in Germany physicians were appointed to the schools to examine especially the eyes and the ears and to see that treatment was applied when necessary From Dr Guye of Amsterdam he had heard that there was a movement to have medical officers for similar purposes in the schools in Holland. The carrying out of any such system would necessitate having a large number of sufficiently trained men. At present the majority of the examining bodies in this country did not recognise that such a thing as a disease of the ear ever occurred and that otology was a necessary part of a student's curriculum, yet diseases of the ear, Mr. Cheatle did not hesitate to say, caused an immeasurably greater amount of loss of health and life than did those of the eye.

Mr. GEORGE MURRAY reported that he had conducted a similar investigation upon the ears of 400 school children in a school at Greenwich. The average age of the children was nine and a half years; he had met with deafness in 18 boys and 25 girls, giving a ratio per 1000 which was similar to that reported by Dr. Rohrer of Zürich.

Dr. S. G. LITTLEJOHN, medical officer to the Hanwell School where Mr. Cheatle's investigations were carried out, raised the question whether residence in a large barrack school increased the number of cases of adenoids and resulting ear disease. Personally he did not think so. He found that the frequency of ear disease increased with the age of the children; age did not necessarily imply long residence. Of those who had discharge from the ear many probably had perforation of the ear before coming into residence in the school, as very few suffered pain before the discharge commenced. He thought that it would be better to have the cases treated in the school under the supervision of a specialist than to board them out.

Dr. W. PERMEWAN (Liverpool) referred to a report made by him in 1896 on 200 children in one of the Liverpool board schools. The children were drawn from the lowest and poorest class. He found that his results agreed with those of Mr. Cheatle. He emphasised the scientific value of the report under discussion and expressed the hope that by a resolution of the society the work would be carried further.

Dr. H. MACNAUGHTON-JONES quoted from tables of cases formerly under his care to show that the causes of ear disease in children arose from diseases incidental to childhood. He inquired what was the latest age at which deaf-mutism could be acquired.

Dr. W. MILLIGAN considered the subject to be one of national interest. The amount of ear disease amongst the children of the poorer classes was appalling and he advocated some systematic and scientific examination of children by the State.

Dr. J. DUNDAS GRANT discussed some of the more unusual lesions met with in the investigation.

Mr. C. H. FAGGE pointed out that the report would not necessarily include the worst cases of deafness occurring in children of the poor as they would find their way to special schools.

Dr. HERBERT TILLEY inquired whether adenoids were not present in greater abundance in all children up to the age of five years.

Dr. W. JOBSON HORNE considered that for the moment they were more concerned with the economic aspect of the whole question than with a consideration of academic details of the lesions so thoroughly investigated and ably classified in the report. The society was evidently contemplating what might be termed an extensive stocktaking of the otological status of the community. That would entail an enormous expenditure of time, careful thought, and patient work, and he trusted that whatever recommendations it might be thought fit to make at some future date to the authorities would be embodied in a scheme which would obviate the issuing of a circular by the Board of Education similar to that issued on Oct. 1st of last year to crown the labours undertaken in the interests of the eyesight of school children.

The PRESIDENT expressed the indebtedness and thanks of the society to Mr. Cheatle for the valuable report which he had presented. He referred to the frequency with which school children were punished by their teachers for errors and omissions due to no fault excepting deafness. He considered that a small committee of the society should be formed to investigate the matter further.

Mr. CHEATLE replied to the several questions that had been put and expressed his thanks to Dr. Littlejohn for the considerable help that he had given in carrying on the investigations.

Resolutions were put and were unanimously carried appointing a committee of the society, consisting of the President (Dr. Urban Pritchard), the two secretaries (Dr. Milligan and Dr. Jobson Horne), and Mr. Arthur Cheatle, Dr. Macnaughton-Jones, and Dr. Permewan, further to investigate the matter and to report.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

Exhibition of Specimens.

A MEETING of this section was held on March 21st, Professor E. H. BENNETT being in the chair.

Dr. T. P. KIRKPATRICK exhibited a specimen of Genito-urinary Tuberculosis. The left epididymis as far as the external ring was hard and enlarged but not painful. Rectal examination detected a nodular enlargement in the left seminal vesicle. The lungs and other organs were healthy; no tubercle bacilli could be found in the sputum. Examination by the x rays gave a negative result. As the symptoms pointed to the kidney the abdomen was opened; the left kidney was found to be enlarged and cystic but the right kidney was normal. On the table the patient became collapsed, the operation could not be continued, and in three days death resulted. The necropsy showed the left kidney to be a semi-solid caseous mass, with little or no renal structure left, and the lumen of its ureter was completely obstructed throughout by a similar substance. The only renal symptoms during life were pain in the back and pain on passing urine which was albuminous. A careful examination of the organs other than those named showed no tuberculous deposit.

Dr. J. B. COLEMAN exhibited the following. 1. A Tumour of the Spinal Cord which he had diagnosed and located during life. It grew from the inner spinal membranes at the level of the eleventh and twelfth dorsal segments of the cord on its right dorso-lateral aspect. It was of about the size and shape of a sweet almond. A microscopical section showed it to be a myxo-sarcoma. 2. A Horseshoe-shaped Kidney, the bond of union being at the lower end of the organ.

Professor BENNETT exhibited a specimen of a Fracture of both Bones of the Forearm immediately above the Epiphyses. The case was a unique one; nothing even resembling it had been recorded. The patient was a girl, about 15 years of age, an inmate of a training school for servants in Dublin, where the accident happened through a fall downstairs on Dec. 8th, 1900, and Professor Bennett saw her on that day. The deformity somewhat resembled that of a Colles's fracture, or an epiphyseal separation of the lower end of the radius, and he applied splints. The following day he found the splints all right and she then told him that at the time of the accident she distinctly heard the bones break. After six weeks he took off the splints and found the bones united. The patient was a plump, well-nourished, good-coloured country girl, who had not complained of any illness and had no sign of physical weakness except an unduly large abdomen and a positive dislike to all food except dry bread; she refused to eat meat, butter, or even sweet cakes. Her only occupation was the folding of tablecloths into lengths for mangling. On Feb. 10th, 1901, he was asked to examine the wrist and to his surprise he found that the deformity had returned. He sent her to Sir Patrick Dun's Hospital and had the wrist skiagraphed. A transverse fracture of both bones just above the epiphyseal line was plainly marked; a cast (which was exhibited) was taken of the limb at the site of the deformity and it had some considerable resemblance to Colles's fracture. The fracture was easily reduced and the patient left the hospital on May 5th, 1901. She returned to the school where she continued to be engaged in light work. Up to this time no other trouble than the broken wrist had been complained of. She, however, still persisted in refusing meat and all other forms of food except dry bread. She was next seen on Jan. 1st, 1902, when Professor Bennett found her much changed for the worse; she was profoundly pallid, of a deeper pallor than that of chlorosis; the spleen was greatly enlarged, there was a certain amount of ascites, and the deformity of the wrist had greatly increased. On Feb. 8th she died. From the time when she left Sir Patrick Dun's Hospital in May, 1901, the deformity of the wrist-joint had gradually but steadily increased. The necropsy revealed no rickety condition; there was no trace of osteomalacia and there was nothing indicative of bone-softening. All the characteristics of pernicious anæmia were present, the fracture was well marked, and the posterior-inferior extremity of the radius ended in a convexity which was well marked and which extended to its inferior articular surface. In scurvy it was known that fractures did not unite and old ones came apart, but this patient's deformity returned when she was apparently in good health. That anæmia was not the cause of the separation of the fragments was beyond question, for it occurred when the patient was not suffering from anæmia and during her stay in a school where the feeding was good.—Dr. J. KNOTT thought that in the return of the deformity and the separation of the fragments the case had some resemblance to that recorded during the severe outbreak of scurvy in Lord Anson's command during his memorable voyage of circumnavigation 1740–1744. He could not find any cause for the non-union other than malnutrition.

BRITISH GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on April 10th, Dr. J. Halliday Croom, the President, being in the chair.—Dr. Macnaughton Jones read notes of a case of Miscarriage and Difficult Labour after Ventro-fixation. He described the firm and extensive adhesion of the uterus to the abdominal wall, as ascertained subsequently when removing an ovarian blood cyst from the same patient, and inferred that ventro-suspension or fixation of the doubled round ligaments (Olshausen's operation) was in women not past child-bearing a safer proceeding than ventro-fixation, the legitimate field for which was a limited one. He also, as bearing on the President's remarks at the last meeting of the society[1] gave the history of a case in which he had on the very next day removed a large multiple myoma without any accident and practically without any loss of blood. The patient passed flatus repeatedly and had no threatening symptoms till the evening of the third day when she complained of sickness. In 12 hours her temperature fell from 99·6° to 97° F., while her pulse ran up from 112 to 136. Persistent coffee-ground vomiting ensued on the following morning. He reopened the abdomen but could find nothing to account for her condition and in spite of all possible treatment she sank very rapidly and died.—The President said that he attributed such coffee-ground vomiting to sepsis. In his experience it had been invariably the precursor of death. He then read a paper on Deciduoma Malignum, as to the etiology of which he said that the latest view was essentially the same as that brought before the society by Dr. Haultain in 1899, the consensus of opinion now being that it was an epitheliomatous new growth the result of pregnancy and derived from the coverings of the chorionic villi, and not a sarcoma; this view was supported by the age of incidence of the disease, from 17 to 55 years, sarcoma being very rare before 35 years. In 60 per cent. of all the cases the disease followed that intense proliferation of the villous epithelium known as myxomatous degeneration of the placenta or hydatid mole; even when this was not the case characteristic symptoms generally appeared within a few weeks, or at most months, of labour or abortion, though one instance had been reported two and another four years after the last known pregnancy. Hæmorrhage, intermittent but so profuse and frequent as to cause profound anæmia, was generally the first symptom and in nearly all cases a characteristic feature, but exceptionally the primary area of active growth, owing to migration of the malignant villi, was deep in the uterine wall or even outside it, in the vagina, ovary, or elsewhere, and naturally hæmorrhage then might not occur. A fœtid discharge mixed with blood-clots and shreds of tissue was common and the early degeneration of the growth was followed by extreme cachexia from absorption of toxins of decomposition, and in default of timely operation the patient, if not carried off by metastases in some vital organ, rapidly succumbed to exhaustion. A case, exceptional in several respects, had been under his own care. A woman, aged 44 years, had had amenorrhœa for four months, leucorrhœa with foul watery discharge suggestive of ordinary malignant disease rather than deciduoma, and had been for some weeks conscious of a swelling in her hypogastrium which extended half-way up to the umbilicus; in her left labium there was a tumour of the size of a walnut, at first supposed to be a cyst of Bartholin's gland, but which proved to be solid and typical deciduoma malignum. The sound when passed into the enlarged uterus seemed to touch friable tissue, but the hæmorrhage, on its withdrawal, was of the slightest, and never since the onset of the amenorrhœa had she had any hæmorrhage whatever; she was nevertheless extremely anæmic and cachectic, sank very rapidly, and lung complications appearing died before it was possible to operate. Her last-known pregnancy had terminated in an ordinary miscarriage six years previously and it was hard to suppose that any products of conception could have remained latent in the uterus for six years and then have undergone malignant proliferation. The only alternative was that the amenorrhœa was due to conception, though she never had any hæmorrhage or other sign of abortion, and except characteristic elements of deciduoma malignum no evidence of pregnancy was found in the uterus.—Specimens of the disease from the uterus and metastases and sections under the microscope illustrated the case.—The discussion turned chiefly on diagnosis, Dr Heywood Smith and Dr. H. Snow speaking and Dr. Macnaughton-Jones reading notes of an incomplete molar abortion simulating deciduoma malignum but apparently completely cured after two years, possibly to recur as malignant hereafter.—The President briefly replied.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—A meeting of this society was held on April 18th, Mr. A. Wynter Blyth, the President, being in the chair.—A discussion on Fixity of Tenure by Medical Officers of Health was opened by Mr. Herbert Jones who referred to a memorandum drawn up by the President and himself showing what had been done during the past 10 years by the society and through its journal and giving the favourable opinions expressed by several Cabinet Ministers and leading statesmen.—Dr. J. Groves alluded to the case of Dr. Cornelius B. Fox, the first medical officer of health of a combined district in Essex, whose representations as to the insanitary conditions of certain villages led to the dissolution of the combination and the loss of his appointment at the end of the three years for which it had been made. The Local Government Board was powerless in such a matter, for the appointment ceased to exist by lapse of time and no authority could be compelled to re-appoint an officer. With regard to the proposal to obtain an improvement in their position by means of special legislation he said that no deputation had been received by any Minister since 1893, when Sir W. Foster was Parliamentary Secretary to the Local Government Board, and Members of Parliament, with very few exceptions, took no interest in what they looked on as a claim for a form of medical monopoly, some, indeed, having declared their intention of blocking such a Bill whenever introduced. There was no chance of its passing unless taken up by the Government of the day and that would never come about until public feeling was aroused to see that security against unmerited dismissal of a medical officer of health was for the good of the community quite as much as for that of the officer. The whole-time officer was in some respects in a less difficult position than the honourable and conscientious half-timer; each had to choose between duty and self-interest, but the latter feared offending his patients no less than the members of his authority. Those only who were willing to do nothing enjoyed a virtual security.—Dr. J. R. Kaye gave a recent and glaring instance of the supersession of an officer who for 22 years had been on the most friendly terms with his boards and the appointment in his place of another who had not applied and who knew nothing of the matter until informed of his election but had declined to accept it. The Local Government Board would not contribute through the county council towards the salary of the medical officer of a combined district if any of the constituent districts paid less than £20, thus leaving the medical officer without even the temporary protection that the State aid conferred.—Mr. T. W. H. Garstang said that even when the relations between the authority and its officer were of the best there was a tendency to shorten rather than to extend the periods of the appointment, and the Local Government Board refused to allow a permanent appointment by any authority if the salary were under £50. Their intention was probably to encourage combination, but in practice he had found it to have the opposite effect. He suggested amending legislation, so that fixity of tenure should, in the case of existing officers, be personal only, except as regards the larger whole-time appointments, and that on the death or resignation of the present holder the county council should make or control the next appointment with a view to amalgamation with adjoining districts.—After further remarks by Mr. P. Targett Adams, Dr. J. W. Hembrough, Mr. H. Beale Collins, Dr. W. H. Symons, and others the consideration of the Bill was referred to the Parliamentary Committee of the Council.

---

[1] THE LANCET, March 22nd, 1902, p. 825.

LIVERPOOL MEDICAL INSTITUTION.—A meeting of this society was held on April 10th, Mr. Rushton Parker, the President, being in the chair.—Dr. Arthur J. Wallace related two cases of the Cæsarean Operation which he had performed on consecutive days. The first patient was a primipara, aged 39 years, who had multiple fibro-myomata, one of which, seven inches in diameter, occupied the right broad ligament. The pelvis was flattened, its conjugate measuring two and a half inches. The patient's condition did not permit immediate supra-vaginal amputation of the uterus, but this was successfully carried out six months later when she was two months pregnant. The second patient, whose age was 27 years, suffered from syphilis and was also a primipara. The pelvis was flattened and generally contracted as the result of hip disease in childhood; its true conjugate measured two and a quarter inches. A layer of greenish tenacious material lay between the membranes and the uterus, presumably diseased decidua. The infant was feeble and developed pemphigus on the sixth day and survived three months. The patient was now again pregnant and had elected to have a second Cæsarean section performed.—The President, Dr. E. T. Davies, and Mr. G. S. Stansfield commented upon points in Dr. Wallace's communication.—Dr. C. J. Macalister read a paper entitled "A Criticism of the Sanatorium Treatment of Phthisis," in which he emphasised the necessity for inquiry into the after-histories of cases in order to obtain data concerning the permanence of the benefits undoubtedly derived by the majority of patients while under treatment. In his experience a large number of patients had relapsed after periods varying from some months to a few years. His impression from this fact and from the statistics of the German Imperial Health Bureau was that while the immediate results were good the ultimate results were disappointing.—Dr. Davies, Dr. W. B. Warrington, Dr. W. Carter, and Dr. J. Barr took part in the discussion.—Mr. Robert Jones read a paper on the treatment of Infantile Spastic Paralysis. He maintained that the affection was strictly surgical and that in suitable cases very marked improvement followed operative measures. In the hemiplegic variety the hand and arm were more seriously involved than was the lower limb. If the paralysis was complete and voluntary relaxation of the spasm was impossible treatment was futile. If the fingers of the affected hand could only be moved in conjunction with those of the opposite side the results were generally discouraging. Wherever any degree of voluntary relaxation was possible apart from associated movement on the opposite side treatment was strongly urged. Tenotomy, tendon transplantation, and hyper-extension of contracted muscles, combined with, and followed by, special exercises, were the indications. For the limbs in spastic paraplegia exsections of portions of the adductor longus and brevis, the horizontal fibres of the adductor magnus, the gracilis, and any other structures opposed to free abduction, should be practised. Exsections or division of portions of the hamstrings and each tendo Achillis were necessary. The limbs were then kept in extreme abduction for three months. Mr. Jones described at length the nature of the exercises to be subsequently prescribed and the methods in which walking should be attempted. A very large number of cases had been operated upon, varying in age from 12 months to 20 years; the benefit resulting was very great, and most children could be made to walk steadily without spasm and for long distances in from 12 months to two years. The classes outside remedial art were the idiot, the microcephalic, and the irritable diplegic with incontinence of urine.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 2nd, Dr. E. C. Kingdon, the President, being in the chair.—Mr. R. C. Chicken showed the following. 1. Two cases of Recovery from Musculo-Spiral Paralysis. In one case the humerus was fractured and the nerve was involved in the resulting callus and in the other case the nerve was damaged by extensive bruising. In both cases the nerve had been carefully dissected out and freed. 2. Several skiagrams of Fracture of the Humerus involving the Elbow-joint, also one of a case of Atlo-axoid Dislocation in a young man. No paralysis had followed the dislocation and no inconvenience other than a stiff neck and pain on forced movements of rotating and nodding the head. 3. A Prostate removed by Freyer's method.—Mr. Chicken then read a paper on When is it Necessary to Open a Joint? He contended that the beneficent advantages of aseptic surgery had not been so fully extended to the various arthropathies as it had to other serous cavities. With thorough aseptic precautions arthrotomy might be fearlessly used for the relief of pain and tension in the more simple effusions, as an aid to diagnosis in all doubtful cases, and to restore nutrition where the trophic influences were impeded by pressure; in addition to those instances where it was urgently demanded for the relief of foreign irritants, such as hæmarthrosis, gonorrheal effusion, &c. He deprecated the use of aspirators and acupuncture needles, preferring a fine long-bladed knife. At present through prolonged tension suppuration was frequently allowed to supervene, tubercle to induce sepsis for want of drainage, and an undiagnosed condition to cause prolonged irritation where an early exploration might have allowed the removal of the primary lesion. Cases were quoted in support of these opinions.—The President, Mr. W. M. Willis, Mr. R. Wood, Mr. R. G. Hogarth, and Mr. J. Thompson discussed the paper, and Mr. Chicken replied.

BRITISH ELECTRO-THERAPEUTIC SOCIETY.—A meeting of this society was held on April 4th, Dr. W. S Hedley, the President, being in the chair.—Dr. Hugh Walsham read an interesting paper on the Diagnosis of Thoracic Aneurysm, &c., by Means of the X Rays. The paper was illustrated by a large number of skiagraphs, shown through the lantern, of thoracic aneurysms, tuberculous bronchial glands, new growths, &c.—The President and Dr A. E. Sansom discussed the paper.—Dr. Sequeira then read a paper on the Finsen Treatment of Lupus, Rodent Ulcer, &c., which was also illustrated by lantern slides, photographs, and many living cases.—After some remarks by Mr George Stoker, owing to the lateness of the hour further discussion was adjourned to the next meeting, to be held on May 2nd. Visitors and members who had kindly promised to take part in the discussion are requested to communicate with the honorary secretary, Mr. Chisholm Williams, 20, Bedford-square, W.C.

FOLKESTONE MEDICAL SOCIETY.—A clinical meeting of this society was held on April 4th, Dr. T. Eastes, the President, being in the chair.—Several cases were shown by members, among these being a *Gumma of the Soft Palate* by Dr. W. J. Tyson, a case of Obscure Nervous Disease by Dr. P. G. Lewis, cases of Supposed *Addison's Disease* and Epithelioma of the Larynx by Dr. A. E. Larking, and Sarcoma of the Femur by Mr. H. Braund. Pathologica specimens were also exhibited.

Reviews and Notices of Books.

Human Embryology and Morphology. By ARTHUR KEITH M.D. Aberd., F.R.C.S. Eng., Lecturer on Anatomy at th London Hospital Medical College. Illustrated. London Edward Arnold. 1902. 8vo, pp. 324. Price 12*s.* 6*d.* net

No doubt can be entertained of the great value of knowledge of embryology to the student of medicine. supplies to the anatomist a satisfactory key to man anomalies and peculiarities in the distribution of nerves an blood-vessels and affords an explanation of many ma formations, cysts, tumours, and the like, that the surgeo is called upon to recognise and to treat. The authors the majority of the older works on physiology who hav dealt with embryology at any length have found it con venient to take the fowl's egg to describe the earlier stage of development, partly because the material for observatio could be easily obtained and the date of incubation precisel determined, and partly because the successive stages of th bird's ovum were much better known than the develop ment of the ovum of the higher animals. But the con tinuous work of many skilled microscopists and mo phologists has of late years rendered our knowledg of the development of the higher animals and man exact as that of the bird and the subject has attained suc portentous dimensions that the authors of the best modern treatises such as those of Foster, Waller, and Starling appear to have felt that it had become unmanageable and either leave it out altogether or give an outline that extends over a few pages only affords to the student a quite inadequate idea of its value and importance. Moreover, embryology is eminently a subject that requires abundant illustration and illustrations are very expensive. There are parts like the uro-genital apparatus that present great difficulties to the learner who is guided and taught only by the text, whilst a diagram immensely facilitates his comprehension of the facts Those who can recall Huxley and Kitchen Parker when discussing the homologies of the bones of the skull will remember how readily the pen or pencil was employed to give point and meaning to their views.

The plan adopted by Dr. Keith in this work differs from that which is followed in most works on embryology. It is customary to commence a treatise on embryology with an account of the sperm and germ cells, with the results of their fusion, and with a description of the medullary folds, the formation of the amnion and allantois, and the succession of changes that succeed the appearance of these structures. Dr. Keith plunges at once into the development of the face, describing the nasal, maxillary, and mandibular processes and pointing out in each case the cause of the malformations that are frequently observed at a later period, such, for example, as cleft palate, hare-lip, macrostoma, and micrognathia. This region, so carefully worked over by Rathke, Huxley, and Parker, is here exceedingly well given and the progress of development is illustrated by many original drawings which the dullest of students can understand. The following excerpt will show how the author leads the learner to understand teratological conditions in the adult by the stages through which the part has passed. Speaking of the premaxillæ he says: "In man each premaxilla is usually ossified by two centres placed side by side. Hence it sometimes happens in cleft palate that the fissure appears not between the canine and lateral incisors but between the lateral and middle incisors. In such cases the two centres of the premaxilla have failed to unite and the cleft occurs between them." The mode of formation of many of the foramina and canals in bone such as the vidian, pterygopalatine, descending palatine, infra-orbital and dental canals, and of the foramen ovale, the foramen rotundum, and the malar canals are concisely given

In successive chapters Dr. Keith describes the development of the pharynx and neck, the organs of hearing, and the teeth, and then devotes two sections to the development of the ovum of the fœtus from the ovum of the mother and to the manner in which a connexion is established between the fœtus and uterus, which includes an account of the primitive ova, the mature ovum, and the formation of the amnion, chorion, and placenta. The uro-genital system is next discussed, and a good chapter is devoted to a part often neglected—the pubo-femoral region, together with the pelvic floor, and fascia. The development of the mammary glands is very clearly and interestingly given. Then follow chapters on the Development of the Spinal Column and Back; the Segmentation of the Body; the Cranium; the Eye and its Appendages; the Nervous, Circulatory, Respiratory, and Digestive Systems; the Body Walls, Ribs, and Sternum; and the Limbs. The author has done wisely in restricting the size of the volume to a moderate compass. We venture to say that all the main facts of human embryology could be mastered by the student in the course of a month's steady application to Dr. Keith's treatise, and we recommend the work as a fairly complete and very trustworthy guide to human embryology. The illustrations are numerous and rather roughly drawn, but they have one excellent feature, that the names of the several parts are printed at the side and well-defined lines are drawn from them to the objects specified. The plan is distinctly superior to letters or figures with footnote references, as such letters are often blurred or rendered indistinct in the printing.

A System of Physiologic Therapeutics: a Practical Exposition of the Methods other than Drug-giving Useful in the Prevention of Disease and in the Treatment of the Sick Edited by SOLOMON SOLIS COHEN, A.M., M.D, Professor of Medicine and Therapeutics in the Philadelphia Polyclinic; Lecturer on Clinical Medicine at Jefferson Medical College; Physician to the Philadelphia Hospital and to the Rush Hospital for Consumption; Consulting Physician to the Jewish Hospital, &c. Volume III.: Climatology; Health Resorts; Mineral Springs. By F. PARKES WEBER, M.A., M.D., F.R.C.P. Lond., Physician to the German Hospital, Dalston; Assistant Physician, North London Hospital for Consumption; Author of "The Mineral Waters and Health Resorts of Europe." With the Collaboration for America of GUY HINSDALE, A.M., M D., Secretary of the American Climatological Association; President of the Pennsylvania Society for the Prevention of Tuberculosis; formerly Lecturer on Medical Climatology in the University of Pennsylvania. In two books. Book I: Principles of Climato-therapy; Ocean Voyages; Mediterranean, European, and British Health Resorts. London: Rebman, Limited. 1901. Pp. 336. Price 21*s*. the volume (Book I.).

THE volume, which has the rather full title-page duly set forth above, is the first book of the third volume of a series written for English and American readers. The greater part of the book before us is the work of Dr. F. Parkes Weber. It is divided into two parts. The first part deals with the physics, physiology, and general therapeutics of climate, and contains chapters on the Atmosphere, on the Effects of Altitude and Aerial Currents, and on Soil and General Topography. The last chapter deals with the Effects of different Classes of Climate A good deal of useful information is summarised in this introductory part of the book; it does not contain, nor does it profess to contain, anything very new or striking. "By desire of the editor theoretic discussions have been confined to fundamentals" There are some useful charts showing respectively the general direction of the better known ocean currents and the mean annual temperature and rainful in various places. A description of the climate of the great American desert which is given on page 67 will probably be new to many English readers. Dr. G Hinsdale explains that its soil differs entirely from that of the deserts of Egypt and Arabia. It is strongly alkaline and irritating to the mucous membranes Salt and borax form important constitutents of the well water It is the hottest and most arid part of North America. It may be worth while to mention that this desert is situated in Arizona, Utah, Nevada, and California and that Mont Diablo and Death Valley are situated in it. Dr. Hinsdale is probably right in saying that this region "can never be made available as a health resort." It is at any rate not one which would commend itself to Englishmen.

The second part of the volume gives a description of health resorts. Ocean climates and ocean voyages are first considered and outlines are given of many trips which may in suitable cases be advantageously undertaken, and at the end of the chapter there is a useful little paragraph as to the contra-indication to sea voyages. However obvious some of this advice may appear to be it is certain that in practice it is not always sufficiently attended to. It is fair neither to the patient nor to his fellow travellers to send on an ordinary passenger ship one liable to maniacal attacks, or to periodic insanity, or having a tendency to commit suicide. A description of the chief European health resorts is arranged in part according to their geographical grouping and in part according to their climate, but, as the author points out, he occasionally makes digressions for convenience of discussion. Practically, in a book of this kind the exact method of classification adopted does not matter much. The work is essentially a book of reference. For this purpose a good and full index is the great desideratum. Without an index the book would have been practically useless, for it is from its very nature not one which would be read straight through for pleasure, nor would it, as a rule, be profitable to adopt such a course. In consulting such a work the medical man generally wishes for information on one of two points. He may either want to know what sort of place is X or he may want to know what places have the best reputation for the treatment of a certain disease. The index of this work is a good one and is so arranged that such information as that suggested may readily be found. A treatise like this must of necessity—as the author very justly observes—be to a great extent a compilation, but an exhaustive compilation of this sort involves a very considerable amount of work and may be well and honestly done, or the reverse. It seems to us that Dr. Weber's book deserves praise and that it will usefully serve the purpose for which it was written, although it would be easy to point out a number of emendations which might with advantage be made. The author is to be commended for acknowledging in so many cases the sources of his information. For Dr. Weber's credit it may be hoped that he is not responsible for the spelling; in this respect the book, like so many of those printed abroad, is very defective.

The Care and Feeding of Children. By EMMETT HOLT, M.D. Second edition, revised and enlarged. London: Henry Kimpton. 1901. Pp. 104. Price 2*s.* 6*d.*

THE methods of technical education, at least so far as this country is concerned, have made little impression on the efficiency of the domestic nurse. Nor have they dispelled that atmosphere of prejudice and ignorance which pervades the practices of the nursery. In fact, the training of domestic nurses is at the present day strictly comparable with that of the monthly nurse or "Gamp" of a generation ago. That is to say, traditions, prejudices, and ignorant practices are perpetuated in unfailing sequence from nurse to nurse and constitute a closed ring of resistance through which it is almost impossible to break. This impenetrable armour of indifference to reform which affects the management and rearing of children constitutes a difficulty which most practitioners fully realise. In America, where the servant question generally, and that of domestic nurses in particular, has already reached a very acute stage, it has been found absolutely necessary to institute practical training schools for nurserymaids where a proper course of instruction can take the place of, or at least precede, the usual nursery apprenticeship. This movement was inaugurated in the year 1889 in connexion with the Baby's Hospital at New York and has, we believe, proved itself an unqualified success, and, further, it has been an active instrument in the dissemination of the most approved scientific teaching with regard to nursery hygiene.

The manual before us has been drawn up by Dr. Emmett Holt for the benefit of nurses who are being trained at the above-mentioned institute in New York. It takes the form of a simple catechism in which the style of question and answer is adapted to the intelligence of girls of about 16 years of age and of the proper class. The contents of this catechism are divided into three parts, the first deals with the care of children, the second with their feeding, and the third with miscellaneous questions which continually present themselves for solution in the daily routine of the nursery. The information contained in this section refers particularly to matters of personal hygiene which ought to be, but are not, perfectly familiar to all those to whose care infants or young children are entrusted. It is the failure to observe these fundamental principles of nursery procedure which is responsible, not only for much of the sickness which is incidental to youth, but also for many of the constitutional diseases which in later years affect adult life. For instance, how many of our domestic nurses realise the importance of maintaining a low temperature in the nursery as the most valuable prophylactic against colds and catarrhs of the respiratory mucous membranes? The following are some of the questions and answers by which Dr. Holt endeavours to impress this truth upon his readers:—

1. At what temperature should a nursery be kept during the night?—During the first two or three months not below 65° F. After three months the temperature may go as low as 55° F. After the first year it may be 50° F. or even 45° F.
2. What symptoms are seen in a child who is kept in too hot a room?—It becomes pale, loses the appetite, shows symptoms of indigestion, occasionally vomits, stops gaining in weight, perspires very much, and takes cold easily, because of this, and also because of the great difference between the indoor and outdoor temperature.

As regards feeding Dr. Holt's well-known system of the home modification of milk by formulæ is taught by the same simple method of question and answer. For example, the pupil is asked, "What are the quantities of the different ingredients (milk, cream, milk-sugar, &c.) needed to make modified milk for an infant of such-and-such an age? Also, how much is required for each feeding and how much for the 24 hours?" The answer in each case is supplied in the form of an easily understood table. By the same simple method of direct question and answer the means of recognising the symptoms of the more common diseases of childhood are impressed upon the pupil in Part III.

Taken altogether this little handbook must be regarded as a very valuable guide to place in the hands of those who are, or of those who intend to be, nurses. It cannot be regretted, however, too deeply that we have in England no institutions in which to employ this little manual or which are in the least comparable with the admirable schools for nurserymaids which have been established by American enterprise in New York, Philadelphia, Buffalo, and Boston.

Hygiene for Students. By EDWARD F. WILLOUGHBY M.D. Lond., Diploma in State Medicine of the London University and in Public Health of Cambridge University. London: Macmillan and Co. 1901. Pp. 563. Price 4*s.* 6*d.*

THIS book, the author explains in his preface, is a fourth edition ("greatly enlarged and improved") of a work which he previously published under the title "Principles of Hygiene" and which was written to serve as a text-book for the examinations of the Science and Art Department. The present edition is divided into six parts which deal respectively with (1) the Health of the Man, (2) the Health of the House, (3) the Health of the City, (4) the Health of the People, (5) Demography, and (6) Meteorology. The sanitary conditions of rural districts are practically ignored, the laws bearing upon sanitation are not touched upon, and little mention is made of unhealthy trades. Demography, the author claims, is treated with greater fulness than in any work not solely devoted to the subject.

The book shows evidence of very careful and painstaking compilation and the author has freely used his judgment as to what he should take and what he should reject. For example, he condemns without exception all chemical methods for the treatment of sewage and he names without hesitation and without circumlocution the filter which should be used for drinking water and in what respects it is superior to all others. This dogmatic teaching is highly commendable when it is accurate and in the most important matters Dr.

Willoughby's views may be readily accepted. There are some statements, however, which will not receive universal approval. The connoisseur in bread will not believe that an oven heated by hot water is superior to the old brick oven, although Dr. Willoughby and a London baker whom he mentions by name agree in recommending the modern invention. The author devotes some space to a disquisition on wine and amongst other things he tells us that for the London market "Chateau Latour" is made by adding nuts or almonds and "Chateau Lafitte" by adding almonds and violets to ordinary Bordeaux wine. "This, however," he adds, "is a totally different thing from fraudulent fabrications." To us such practices appear to partake rather of the nature of fraud. From what has been said it will be gathered that the book is somewhat discursive. It contains statements of opinion on matters which have no special interest for students and which are beyond the purview of the ordinary examiner. On the other hand, the author omits to deal with subjects which form an important part of the study of hygiene. For these reasons we fear that the work, portions of which are excellent, will prove less useful than it might otherwise have been.

LIBRARY TABLE.

Vade Mecum d'Obstétrique et Gynécologie. By Dr. HENRI FISCHER. Paris: L. Boyer. 1902. Pp. 321. Price 4 francs 50 centimes.—This little book, which we see the author intends to have translated into English, consists of a series of short lectures upon obstetrics and gynæcology. It is written in the colloquial style of lectures and contains a good deal of information. The design which the author has had in writing the book is to place before the student simple rules to guide him in his choice of operative measures in the various conditions considered. The value of the different procedures is not discussed and no reasons are given for their choice. The book is necessarily incomplete and, dealing as it does with but a limited part of the subject of obstetrics and gynæcology, is not of much value. We are afraid that an English translation is not likely to meet with much success in this country.

Guide de l'Examen Gynécologique. By Dr. LEON ARCHAMBAULT. Paris: A. Maloine. Pp. 116 1902. Price 3 francs.—This book is an elementary guide to gynæcological examination. In contains a limited number of facts relating to the subject described shortly and simply. It might prove of some use to junior students and *lycéens.* We see but little advantage in the publication of such books, containing as they do nothing that cannot be better learnt from the larger text-books on the subjects, and we do not think that their use by students is to be encouraged. This form of book is not one that we can recommend.

Essai de Séméiologie Urinaire. (An Essay on Urinary Symptomatology.) By CAMILLE VIEILLARD, Pharmacien-Chimiste, Membre de la Société Chimique de Paris; with a preface by ALBERT ROBIN. Paris: Société d'Éditions Scientifiques 1902. 8vo, pp. 376. Price 6 francs.—The first thing that strikes us in reading this book is the large amount of unnecessary verbiage in its pages. The style is somewhat pedantic and makes reading tedious. Such faults could, no doubt, be overlooked if the subject-matter were in itself excellent. But there is practically nothing new, except in the appendix, which is devoted to cryoscopy as a means of examination of the urine. The book is divided into three parts, the first dealing with the general principles of urinary semeiology, the second with each normal and abnormal constituent of the urine in turn and the meaning of its presence therein, and the third with what the author calls "urologic syndromes." The introductory remarks occupy 18 pages and are chiefly historical. The author claims to treat the whole subject from a novel point of view. In the first part of the book, on page 68, will be found a copy of a somewhat curious document—a form on which to record a complete analysis of urine. It will be seen that Professor Bouchard, whose system this is, lays stress on the anthropometrical examination of the patient as well as on the chemical analysis of his urine. The observer has to note down the patient's complexion, muscular condition, weight, size, circumference of waist, and the total superficies of his body. Dr. Bouchard says that the determination of the skin area is as useful as analysis of the urine when viewed in conjunction with it and that without the former the results of the examination are unsatisfactory. This seems to us to be urine-testing extraordinary and we can hardly regard Dr. Bouchard's method as a practicable one, always supposing that this account of it is correct. M. Vieillard does not seem to be sure about his views on this teaching, but on the whole he criticises it unfavourably. The second part of the book is more serviceable and might well stand by itself, for neither the first nor the third part is of much value. Then comes the Appendix on Cryoscopy which occupies 28 pages, devoted to what seems to be a mode of examining urines by physics rather than by chemistry. The author has previously published a brochure on this subject. Cryoscopy (*κρύος* ice, *σχοπεω* I see) is a method of estimating the quality of urines by observations of their freezing-point, which is found to vary with the amount of solids they contain dissolved; different substances are said to alter the freezing-point in proportion to their molecular weight. This, at any rate, is what we understand by the easy-going account of which the appendix consists. The author takes 6000 as the molecular weight of albumin and doubtless if this were known to be the case calculations would be much simplified. It is unproved, however, as far as we can ascertain. In the last paragraph in the book M. Vieillard states that these ideas are mostly new and that some modifications may be necessary. In this we quite agree with him, for we should be sorry to accept all that he says about cyroscopy without question or criticism.

Pharmacopœia of the Hospital for Diseases of the Throat, Nose, and Ear, Golden-square. Edited by H. LAMBERT LACK, M.D. Lond., and CHARLES A. PARKER, F.R.C.S. Edin., surgeons to the hospital. Sixth edition. London: J. & A. Churchill. 1901. Pp. 75. Price 2*s.* 6*d.*—The authors state that they have made numerous omissions of obsolete drugs, whilst they have added fresh prescriptions, the most important of which will be found in the nasal douches, local anæsthetic solutions, and mixtures and pills for internal use. The metric system of weights and measures has been introduced in addition to the old system, and the quantities under the metric system are said not to be the exact equivalents of those of the old system, but, save in fractional differences, the preparations made up by both systems will contain the same proportions of ingredients. The following acids have been added: chromic, nitric, and trichloracetic, which are grouped together under the title "Caustica," London paste, which had appeared in previous editions, being now discarded. It is stated in this edition, as in all previous ones, that if *porte caustiques* are used there is always the risk of a portion of the caustic becoming detached and falling into the throat. This would rather depend upon the part of the upper respiratory tract to which the caustic was applied. The medicated bougies for nasal use have been most wisely omitted. The alkaline nose-wash is reduced in strength and is made to correspond more nearly with Dobell's solution by the addition of sugar. The more important additions in the sub-section on douches are *collunarium ammonii chloridi*, antipyrine, benzoini, boracis cum spiritu being substituted for boracis cum sale. Eucalypti compositum, menthol compositum, phenol compositum, phosphatis compositum, potassii chloratis, and sanitas are also new. Fuming inhalations are omitted entirely. Gargles have undergone some alterations of no great importance. Salicylic acid drops are the only noticeable addition to the guttæ. Hypodermic injections make their appearance in this edition. All the insufflations—aural, nasal, and laryngeal—have undergone reduction in their numbers. Local anæsthetic solutions appear under a different heading and include several useful preparations. The mixtures present no noteworthy changes, but the watery vapours or sprays have been entirely revised and five prescriptions are given for oil solutions to be used with the volatiliser. The rest of the book contains nothing worthy of notice. The authors are to be congratulated on having performed in a very able way a task which must be extremely irksome, for the edition exhibits a marked superiority over that issued seven years ago.

Atlas der Krankheiten der Nasen, der Nebenhöhlen und des Nasenrachenraumes. Von Privat-docent Dr. P. H. GERBER in Königsberg. Achte (Schluss) Lieferung. (*Atlas of Diseases of the Nose and its Accessory Cavities and of the Naso-Pharynx.* By Dr. P. H. GERBER of Königsberg. Eighth Part.) Berlin: S. Karger. 1902. Price 6*s.* each part.—Dr. Gerber's concluding number deals in its first Plate (No. XXXVII.) with a disease of wide interest but endemic in a more or less restricted area—that is to say, rhino-scleroma; the figures will be of great assistance in preventing errors in diagnosis in this rare disease. The remaining plates are devoted largely to special conditions, such as various forms of eczema, herpes, erysipelas, atheroma, elephantiasis, leprosy, and so on, as they affect the nose. One plate is devoted to affections of the external nose, another to congenital anomalies, while the final plate contains examples of diseases described previously. By this *Lieferung* Dr. Gerber fully maintains the standard of excellence shown in the earlier ones. As we have remarked in notices of the previous parts, we consider this to be an atlas of the highest excellence and of undoubted utility; in fact, as an aid to teaching the value of books of this description cannot be over-estimated.

The Book of Old-fashioned Flowers and Other Plants which Thrive in the Open-air of England. By HARRY ROBERTS, author of "The Chronicle of a Cornish Garden." London and New York: John Lane. 1901. Pp. 112. Price 2*s.* 6*d.* net.—This is the fourth volume of the series of handbooks on practical gardening which have been produced under the general editorship of Mr. Harry Roberts and of which the first three treated respectively of the culture of asparagus, of greenhouse flowers, and of the grape. The present volume is a useful and pretty little book which will be read with pleasure and profit by everyone interested in hardy flowers. The book is not, and does not profess to be, a systematic treatise, but it contains a good deal of information some items of which will be new to most readers and much of the advice given is excellent. The importance which should be attached to the preparation and use of "compost" is often ignored by amateur gardeners, but compost to the gardener is strictly comparable with the "stock" of the cook. Mr. Roberts's idea that, regarded as decoration, cut flowers are "inappropriate and childish" is not one which will generally commend itself and he is perhaps unnecessarily severe on those who admire the playful artistic spirit which led to the carving of yews and other trees into dragons, pagodas, and peacocks. These things, however, are merely matters of taste and there is only one point in the book to which we must take serious exception. "For weedy paths," the author says, "all that is now required is to water the paths when dry with a solution made by boiling five ounces of powdered arsenic in a gallon of water, stirring the while and then adding two gallons of cold water and half a pound of soda." We cannot commend this wholesale use of arsenic nor do we think that the poison should be intrusted to the gardener. A case recently came to our notice in which it seemed probable that a large number of big trout were killed by the adoption of the practice recommended by Mr. Roberts. In this instance there was a heavy rainfall soon after the application of the mixture, much of which must have been carried into the lake by the flood water.

Banking. By A. D. COCHRANE. London: Effingham Wilson. 1902. Pp. 99. Price 2*s.* 6*d.*—From the point of view of general education everybody ought to know something about the subject of banking and medical men may profit by a perusal of the pages of this book. Starting with an account of the origin of banking, the author points out that Greece, Rome, and Jerusalem were each responsible for the commencement or development of some one division of the system which is known as banking at the present day. In successive chapters he deals with early banking and political influences, the cause of failures, American banking, the position of London as the clearing-house of the world, the growth of joint-stock banks, gold reserve, savings-banks, and banking as it is at the present day. "Banking Customs" is not the least interesting chapter and explains many of the rules which are adopted by banks for their protection in the conduct of their business and which appear to their customers to be simply "red tape."

JOURNALS AND MAGAZINES.

American Journal of the Medical Sciences.—Amongst the original articles in the issue of this journal for April is one by Dr. Charles Phelps, surgeon to the Bellevue and St. Vincent's Hospitals, New York, on Localisation of the Mental Faculties in the Left Prefrontal Lobe. The writer reports numerous cases of injury to the head and also the conclusions at which he has arrived after the study of a large number of similar cases which have been reported. The large number of cases cited (800) is fully sufficient to form a basis for such conclusions. Three generalisations were made: 1. In every instance but two in which consciousness was retained or regained and the mental faculties were not perverted by general delirium laceration involving the left frontal lobe was attended by default of intellectual control and the lesion was usually, if not always, of the prefrontal region and implicated either its superior or inferior surface. Subcortical disintegration, or deep or extensive laceration of the cortex, was specially characterised by abrogation of mental power and superficial laceration by aberration in its manifestations. 2. In every instance in which laceration was confined to the right lobe the mental faculties were unaffected, except in so far as they were obscured by stupor or delirium occasioned by coincident general lesion. 3. Compression or contusion of the left lobe only exceptionally produced specific intellectual disturbance. The other communications in this number include: On the Effect of Severing and of Mechanically Irritating the Vagi, by Dr G. W. Crile; An Experimental Investigation into the Causes and the Treatment of Diabetes Mellitus, by Dr. A. C. Crofton; and Primary Tuberculosis of the Liver, by Dr. Louis Frank.

The *Practitioner* in its April issue contains fewer original communications than usual. Dr. Theodore Dyke Acland presents a Clinical Study of Bronchiectasis which is long and well illustrated by cases and which gives a fairly comprehensive view of this most hopeless affection. Dr. Acland's conclusions with regard to some of the newer forms of treatment are depressingly despondent though we feel sure that they are justified by results up to the present. Mr E. Treacher Collins writes on Ophthalmia Neonatorum and has been at great pains to collect some valuable facts from both home and foreign sources. He rightly insists upon the preventability and great importance of preventing this disease which is the cause of blindness in such a large percentage of all cases.

Analytical Records

FROM

THE LANCET LABORATORY.

BILLON'S "OVO" LECITHIN PILLS AND GRANULES

(BILLON'S OVO LECITHIN DÉPÔT, 16, WATER-LANE, GREAT TOWER-STREET, E.C.)

IT has been said that phosphorus is to the nervous tissues what iron is to the blood corpuscles. The difficulty as regards administration, however, has been to present phosphorus in a suitable form. The animal substance lecithin which is a constituent of all nerve matter and is found also in eggs would appear to be a very favourable form of exhibiting phosphorus, judging from the excellent results which its administration is giving in disturbances of general nutrition due to nervous disorder and in anæmia and wasting disease. *Billon's lecithin* is extracted from the yelk of the egg by a special process. It is identical with distearine glycerophosphate of choline and possesses a faint odour resembling that of fish oil. The granular preparation occurs in short thick threads of a dull yellow colour easily soluble in water, the solution readily frothing and possessing a sweet vanilla like taste On suitable treatment the reactions for glycerine, choline, and phosphorus may respectively be obtained. Billon's ovo lecithin may also be procured in the form of pills and a liquid preparation is available for hypodermic injection. There is abundant clinical evidence to show that these preparations have a marked tonic effect.

"CHURNO" (BUTTER SUBSTITUTE)

(VAN DEN BERGHS, LIMITED, 21, MINCING-LANE, LONDON, E.C)

According to our analysis the following is the proximate composition of "Churno" moisture, 12·75 per cent., fat, 83·55 per cent., and curd and salt, 3·70 per cent. The examination of the fat proved the preparation to be a butter substitute as described. It contains a minimum amount of water and is of a palatable flavour which is decidedly like that of good butter The sample which we examined was in sound condition, sweet and fresh to the taste, and free from rancidity. "Churno" is a wholesome food and serves as a good substitute for butter, while it is sold for half the price.

LEVURINE

(CH COUTURIEUX, PARIS AGENTS: MESSRS ROBERTS AND CO., 76, NEW BOND-STREET, LONDON, W)

Levurine is a specially prepared barm obtained by culture, so that a particular "race" of yeast is selected According to our experiments it is exceedingly active, for on adding a pinch to a solution of glucose brisk fermentation is speedily set up. Levurine possesses a faint yeasty smell which is accompanied by the smell of some aromatic used probably for preserving purposes. According to Dr Doyen of Paris levurine appears to exert a remarkable restraining effect upon the activity of the pus organism It is said to act as a real specific, its action being comparable with that of the antitoxin serum in diphtheria. In a case of anthrax it is stated that the furuncle and the anthrax subside and the inflammation diminishes just as the inflammatory œdema disappears in diphtheria. In a case of a painful boil on the leg after the administration of levurine, when the centre had already softened, the absorption, it is reported, took place only on the third day and the inflammatory swelling disappeared in some hours "The core was eliminated three days after and the wound was in a fair way of cicatrisation" The evidence would appear to show that levurine is decidedly antagonistic to the staphylococcus pyogenes, and this barm certainly merits a trial in this country similar to that already accorded to it in France.

MEDICATED SOAPS

(CHARLES MIDGLEY, LIMITED, 23, ST ANN'S-SQUARE, MANCHESTER.)

We have carefully tested these soaps, having regard to the statement that they are superfatted. This is practically borne out since the phenolphthalein test, except in one case, gave no indication of the presence of free alkali. The exception was the traumatol soap, traumatol being an iodised cresylic compound. Traumatol soap contains 5 per cent of traumatol, a very powerful yet not irritating antiseptic equal in germicidal power to corrosive sublimate In the same way we examined nicotine soap, containing 10 per cent. of nicotine, intended for the treatment of scabies, formaldehyde soap, containing 5 per cent. of formaldehyde and sulphur; and camphor soap. The nicotine soap tends to excite sneezing, while the formaldehyde soap has a necessarily pungent odour The soap basis throughout is evidently of a superior kind.

ANDERSON'S TAFELWEINE

(GEORG ANDERSON, FRANKFORT-ON-MAIN)

The feature of these wines is their practical freedom from sugary constituents, the amount of sugar seldom exceeding one fifth per cent. The wines are of the hock type, light and delicate and suitable in particular for those who are prohibited the free use of sugar in any form. We examined three samples with the following results. No. 1 extractives, 1·55 per cent., mineral matter, 0·21 per cent., alcohol, by weight 9·36 per cent., by volume 11·61 per cent., equal to proof spirit 20·35 per cent., volatile acid reckoned as acetic acid, 0·19 per cent.; fixed acid reckoned as tartaric acid, 0·32 per cent.; and sugar, 0·20 per cent. No 2 extractives, 1·62 per cent., mineral matter, 0·18 per cent., alcohol, by weight 10·08 per cent., by volume 12·49 per cent., equal to proof spirit 21·89 per cent, volatile acids reckoned as acetic acid, 0·16 per cent, fixed acids reckoned as tartartic acid, 0·26 per cent., and sugar, 0·25 per cent. No. 3 extractives, 1·76 per cent., mineral matter, 0·16 per cent., alcohol, by weight 9·36 per cent., by volume 11·61 per cent., equal to proof spirit 20·35 per cent., volatile acids reckoned as acetic acid, 0·07 per cent.; fixed acids reckoned as tartaric acid, 0·36 per cent.; and sugar, 0·24 per cent. The wines present no striking differences in composition. They are decidedly dry and not expensive,

KALARI BISCUITS

(CALLARD AND CO., 65, REGENT-STREET, LONDON, W)

Though presenting the texture and crispness of an ordinary kind of biscuit the kalari biscuit is both starchless and sugarless Further, it is free from excess of fat, which is frequently an objectionable feature in food prepared especially for the needs of those suffering from diabetes or obesity In spite of the fact that the kalari biscuit is quite free from carbohydrates it is palatable, while on account of the high proportion of proteids it is undoubtedly nutritious. Kalari bread is made on the same basis.

MEDICAL MAGISTRATE — Mr. John Sidney Turner, M.R.C.S. Eng., F.L.S., has been appointed by the Lord Chancellor a Justice of the Peace for the County of Kent.

New Inventions.

TRACHEOTOMY INSTRUMENTS.

IN certain cases of diphtheria after tracheotomy the trachea exudes a gummy secretion of great tenacity which not only necessitates very frequent cleansing of the inner tube but renders its removal difficult. There is then risk of the nurse pulling both tubes together from the shield, and I have known this happen both with Parker's tubes and my own. The very simple contrivance figured (Fig. 1) renders such an accident impossible but it can only be used with tubes of my pattern. It is made of aluminium wire guarded at the ends with rubber and it is held in the palm of the right hand by means of the second finger crooked round the angle, leaving the thumb and the index-finger free. The instrument being gently pressed (Fig. 2) against the wings of the outer tube the handle of the inner is grasped between the index-finger above and the thumb below, and a good pull can now be exerted with perfect safety by the use of one hand only; further, the outer tube is held steady by the instrument and is not jogged about in the trachea.

FIG. 1.

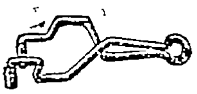

FIG. 2.

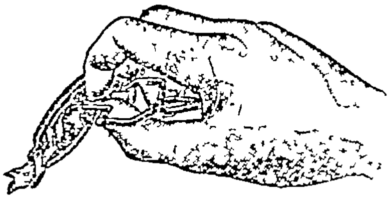
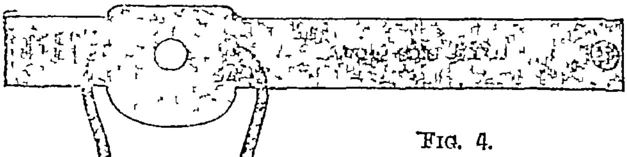


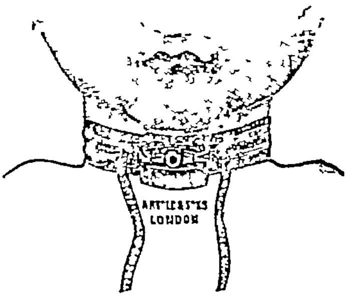
The method of dressing tracheotomy wounds frequently adopted is messy and untidy; by the use of the bandage figured (Fig. 3) these drawbacks are removed. It is made of pink jaconet, lined, except near the wound, with flannel, and it can be washed. Buttoned round the neck it holds the deep dressing firmly applied to the wound, while protecting it from contamination by discharges from the tube or elsewhere (Fig. 4.) This dressing need, therefore, be disturbed but rarely—once or twice in 24 hours. The tapes attached, also coloured pink for distinction, are tied in a bow over the superficial dressing, while the white tapes of the tube lie on the bandage and so do not fret the neck. Tube, dressing, and bandage are usually put on and taken off together, and in such case a mere hole in the last two suffices; if the tube is already in, however, then they must be slit. Coarse adjustment for different necks is attained by three sizes of bandage and fine adjustment by four buttonholes to each. The tubes shown are those which I described previously,[1] the only change which I have made being to bring the handle of the inner tube down lower. They are easier to clean during and after use than either Parker's or Durham's. The dilating director figured at that time has proved very serviceable—indeed, I have never even put out another for two years; it is simpler than any other pattern of dilator. The above are all made by Messrs. Arnold and Sons.

FIG. 3.



The bandage.

FIG. 4.

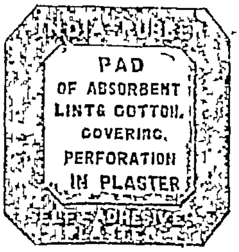


The bandage applied.

G. C. GARRATT, M.B. Cantab.,
Assistant Resident Medical Officer, London Fever Hospital.

NEW VACCINATION PAD.

THIS pad, introduced under the name of the "Limpet," is made of absorbent lint and cotton-wool, mounted on self-adhesive indiarubber plaster, the ample margin of the material which is provided ensuring the pad remaining firmly in position and this without any unpleasant constriction of the arm such as is caused by the use of tapes, &c. The pad remains firmly attached and is an efficient and comfortable protective covering. The pads are made in two sizes, children's to retail at 2*d.* and adults to retail at 3*d*, by Solport Brothers, 188, Goswell-road, London, E.C.



Looking Back.

FROM

THE LANCET, *SATURDAY, APRIL* 17, 1824.

ST. THOMAS'S HOSPITAL.

April 15.

HENRY PRINCE, the little child from whom Mr. TRAVERS extracted a urinary calculus, on the 12th ultimo, has now perfectly recovered from the effects of the operation, and is entirely free from symptoms of stone. In giving the concluding notice of this child's case, we cannot refrain from pointing out to the benevolent governors of St. Thomas's the forlorn and hopeless prospect of this poor little infant. Through their benevolence and the skill of their medical officers, he is restored to health, but if their kindness be not extended beyond the limits usually prescribed to the patient of the hospital, we apprehend his rescue from death will prove rather a source of misery than happiness. We are informed that he is the offspring of parents who have had the inhumanity to forsake him, and who have consigned his welfare to the casual stranger. Should this child, now scarcely more than two years of age, be discharged from the hospital, we believe it is uncertain even to what parish he will be sent, much less to what friend; therefore unless the governors humanely interfere to shield this infant and continue their protection, we fear they will only have kept him from one grave to which he was fast approaching for the purpose of sending him by a more painful and harrassing route to another. Now as we know that many of the governors peruse the columns of THE LANCET, we hope they will take the distressing circumstances of this orphan's case into consideration, and protect him from that want to which we fear he will otherwise be inevitably doomed.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly court of the directors of the society was held on April 9th, at 11, Chandos-street, W., the President, Mr. Christopher Heath, being in the chair The report for 1901 was read. Seven new members were elected and the deaths of four members were reported. Applications for the renewal of grants were read from 52 widows, 11 orphans, and five recipients from the Copeland Fund, and a sum of £1282 was voted to be given at the next court. Two fresh applications from widows were read and grants were made. Donations amounting to £221 15*s.*, including £200 from the executors of Miss *C. A. Birch*, were announced. *Nine members were* nominated for election at the annual general meeting to fill the vacancies in the court of directors. The expenses of the quarter were £58 5*s.* The annual general meeting will be held on May 21st, at 5 P.M.

THE LANCET.

LONDON SATURDAY, APRIL 19, 1902

Cancer Research.

ALTHOUGH it is still disputed by some authorities we fear it is only too sadly true that within the last 30 years there has been a notable increase in the prevalence of cancer and other forms of malignant disease. The fact has been borne in upon the mind of the public as well as upon the medical profession and the result is a very general interest in, and a painful anxiety to fathom, the mystery that now enshrouds the whole subject of malignancy. The last 30 years has been a period also of great advance in medical knowledge and consequent improvement in our means of preventing or dealing with disease. It has witnessed the great results with which the name of LISTER will ever be associated, the secret of tuberculous disease has been laid bare by KOCH, and diphtheria has been robbed of much of its terror by the "serum treatment." But what has science done to unravel the tangled problem of cancer? What new powers have we of combating this scourge? The surgeons are ever widening their field of operation; they practise more extensive removal of parts, and often they are enabled by the public confidence in surgery to treat the disease at an earlier period of its history than before. The results are seen in a lessened mortality from their operations and a greater freedom from recurrence of the disease. But the most optimistic surgeon must confess that his art falls far behind his desire and of the other means at his disposal for combating malignant disease he can speak with only less confidence. This is known to the public just as fully as to the profession and it is therefore extremely natural that the public should be urging the profession to increase its efforts to discover the cause of, and the proper treatment for, cancer.

As is well known to our readers, it is proposed to raise £100,000 and to hand over this sum to a committee to be used for the sole and special purpose of investigating cancer. The Royal College of Physicians of London and the Royal College of Surgeons of England have drawn up a "scheme for the organised investigation of cancer" which is published in another part of our present issue. We need not assure our readers that we view every skilled investigation of cancer, from any standpoint whatever, with the very strongest sympathy and our columns have always been open for the recording of scientific results. There is no department of pathological research in which we and all our readers take a deeper interest than in the study of cancer; there is no branch of medical practice in which some great advance would be so welcome as in the treatment of cancer, and the impulse which gave birth to the scheme now before us has our deepest sympathy. But as we read the "scheme" which has now been promulgated by the two Royal Colleges we feel that it falls somewhat short of what we should have expected from such a source. To the rich man to whom the appeal for money is now made we would say, "It is vastly easier to give princely sums than to solve nature's problems." To the organisers of this investigation and the draughtsmen of the scheme we would say, "The work will be done by the scientific investigator, the patient toiler in laboratory or hospital ward, and not by any committee, consultative, advisory, or executive." The scheme before us appears to have been drawn up in forgetfulness of these truisms. There are to be two committees—the general committee and the executive committee. Of what service the general committee is to be to a very difficult scientific investigation it is impossible to imagine. We notice, too, that the executive committee, which is to have the real control of the fund and therefore of the work to be undertaken, is partly composed of *ex officio* members and it is no secret that those *ex-officio* members may not be in any way specially qualified to assume this responsibility. It seems to us that those who drew up this scheme have devoted too much thought to the construction of the committees—the flies on the wheel—and too little thought to the scientific investigators. Yet any one who sits down and thinks the matter out must see at once that cancer remains a mystery, not for lack of a committee, or of any grand scheme of collective investigation, or of big volumes of statistical, dietetic, and topographical information, but from lack of scientific observation and knowledge gained by highly trained workers. To solve the problem of cancer the real difficulty lies in getting the right workers, not in getting the right sum of money. How are they to be got? By wide scientific training in properly equipped laboratories. The question therefore naturally arises whether, if large sums of money are forthcoming for this work, they will not be more wisely spent in securing the highest possible training of suitable men in the most perfect methods of scientific research of all kinds than in continuing work along the narrow lines at present pursued. We have the fullest sympathy with the suggestions to subsidise individual workers, we should like to see all such men not only provided with due means for carrying out their investigations but also set free to devote their entire energies to the work in hand. Only too often in this country important scientific researches have to be made in the short hours than can be snatched after the pressing claims of a practice have been met and they are liable to grievous interruptions. It should be the ambition of the rich to bear their share in scientific progress by enabling such workers to devote their best energies to their highest call.

We notice that the first object of this fund is "to provide, extend, equip, and maintain laboratories to be devoted *exclusively* to cancer research" (the italics are ours). If we knew that malignant disease was something quite distinct from every other morbid process in the human body there might be some justification for this "exclusiveness." But in default of this knowledge it seems to us unwise thus to limit the purview of those supported by this fund. None can tell from what direction the great discovery will come—from physics, chemistry, or biology in its widest sense. It is, indeed, very probable that he who looks only at cancer will fail to "see" it. While, therefore, we feel in every way desirous that further and clearer light may be thrown on the mystery of malignancy, and to that

New Inventions.

TRACHEOTOMY INSTRUMENTS.

IN certain cases of diphtheria after tracheotomy the trachea exudes a gummy secretion of great tenacity which not only necessitates very frequent cleansing of the inner tube but renders its removal difficult. There is then risk of the nurse pulling both tubes together from the shield, and I have known this happen both with Parker's tubes and my own. The very simple contrivance figured (Fig. 1) renders such an accident impossible but it can only be used with tubes of my pattern. It is made of aluminium wire guarded at the ends with rubber and it is held in the palm of the right hand by means of the second finger crooked round the angle, leaving the thumb and the index-finger free. The instrument being gently pressed (Fig. 2) against the wings of the outer tube the handle of the inner is grasped between the index-finger above and the thumb below, and a good pull can now be exerted with perfect safety by the use of one hand only; further, the outer tube is held steady by the instrument and is not jogged about in the trachea.

FIG. 1.

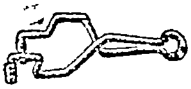

FIG. 2.

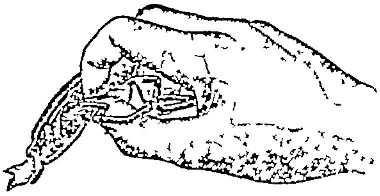

The method of dressing tracheotomy wounds frequently adopted is messy and untidy; by the use of the bandage figured (Fig. 3) these drawbacks are removed. It is made of pink jaconet, lined, except near the wound, with flannel, and it can be washed. Buttoned round the neck it holds the deep dressing firmly applied to the wound, while protecting it from contamination by discharges from the tube or elsewhere (Fig. 4.) This dressing need, therefore, be disturbed but rarely—once or twice in 24 hours. The tapes attached, also coloured pink for distinction, are tied in a bow over the superficial dressing, while the white tapes of the tube lie on the bandage and so do not fret the neck. Tube, dressing, and bandage are usually put on and taken off together, and in such case a mere hole in the last two suffices; if the tube is already in, however, then they must be slit. Coarse adjustment for different necks is attained by three sizes of bandage and fine adjustment by four button-holes to each. The tubes shown are those which I described previously,[1] the only change which I have made being to bring the handle of the inner tube down lower. They are easier to clean during and after use than either Parker's or Durham's. The dilating director figured at that time has proved very serviceable—indeed, I have never even put out another for two years; it is simpler than any other pattern of dilator. The above are all made by Messrs. Arnold and Sons.

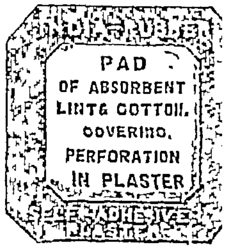
Assistant Resident Medical Officer, London Fever Hospital.

NEW VACCINATION PAD.

THIS pad, introduced under the name of the "Limpet," is made of absorbent lint and cotton-wool, mounted on self-adhesive indiarubber plaster, the ample margin of the material which is provided ensuring the pad remaining firmly in position and this without any unpleasant constriction of the arm such as is caused by the use of tapes, &c. The pad remains firmly attached and is an efficient and comfortable protective covering. The pads are made in two sizes, *children's to retail at 2d. and adults to retail at 3d.*, Solport Brothers, 188, Goswell-road, London, E.C.



Looking Back.

FROM

THE LANCET, *SATURDAY, APRIL* 17, 182

ST. THOMAS'S HOSPITAL.

April 15.

HENRY PRINCE, the little child from whom Mr. TRAVE
extracted a urinary calculus, on the 12th ultimo, has n
perfectly recovered from the effects of the operation, a
is entirely free from symptoms of stone. In giving t
concluding notice of this child's case, we cann
refrain from pointing out to the benevolent governc
of St. Thomas's the forlorn and hopeless prospe
of this poor little infant. Through their benevolen
and the skill of their medical officers, he is restored
health, but if their kindness be not extended beyond t
limits usually prescribed to the patient of the hospital,
apprehend his rescue from death will prove rather a sour
of misery than happiness. We are informed that he is t
offspring of parents who have had the inhumanity
forsake him, and who have consigned his welfare to t
casual stranger. Should this child, now scarcely more th
two years of age, be discharged from the hospital,
believe it is uncertain even to what parish he w
be sent, much less to what friend; therefore unless t
governors humanely interfere to shield this infant and co
tinue their protection, we fear they will only have kept hi
from one grave to which he was fast approaching for t
purpose of sending him by a more painful and harrassi
route to another. Now as we know that many of t
governors peruse the columns of THE LANCET, we hope th
will take the distressing circumstances of this orphan's ca
into consideration, and protect him from that want to which
we fear he will otherwise be inevitably doomed.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly court of the directors of the society was held on April 9th, at 11, Chandos-street, W., the President, Mr. Christopher Heath, being in the chair. The report for 1901 was read. Seven new members were elected and the deaths of four members were reported. Applications for the renewal of grants were read from 52 widows, 11 orphans, and five recipients from the Copeland Fund, and a sum of £1282 was voted to be given at the next court. Two fresh applications from widows were read and grants were made. Donations amounting to £221 15*s*., including £200 from the executors of Miss C. A. Birch, were announced. Nine members were nominated for election at the annual general meeting to fill the vacancies in the court of directors. The *expenses* of the quarter were £58 5*s*. The annual general meeting will be held on May 21st, at 5 P.M.

Cancer Research.

ALTHOUGH it is still disputed by some authorities we fear it is only too sadly true that within the last 30 years there has been a notable increase in the prevalence of cancer and other forms of malignant disease. The fact has been borne in upon the mind of the public as well as upon the medical profession and the result is a very general interest in, and a painful anxiety to fathom, the mystery that now enshrouds the whole subject of malignancy. The last 30 years has been a period also of great advance in medical knowledge and consequent improvement in our means of preventing or dealing with disease. It has witnessed the great results with which the name of LISTER will ever be associated; the secret of tuberculous disease has been laid bare by KOCH; and diphtheria has been robbed of much of its terror by the "serum treatment." But what has science done to unravel the tangled problem of cancer? What new powers have we of combating this scourge? The surgeons are ever widening their field of operation, they practise more extensive removal of parts, and often they are enabled by the public confidence in surgery to treat the disease at an earlier period of its history than before. The results are seen in a lessened mortality from their operations and a greater freedom from recurrence of the disease. But the most optimistic surgeon must confess that his art falls far behind his desire and of the other means at his disposal for combating malignant disease he can speak with only less confidence. This is known to the public just as fully as to the profession and it is therefore extremely natural that the public should be urging the profession to increase its efforts to discover the cause of, and the proper treatment for, cancer.

As is well known to our readers, it is proposed to raise £100,000 and to hand over this sum to a committee to be used for the sole and special purpose of investigating cancer. The Royal College of Physicians of London and the Royal College of Surgeons of England have drawn up a "scheme for the organised investigation of cancer" which is published in another part of our present issue. We need not assure our readers that we view every skilled investigation of cancer, from any standpoint whatever, with the very strongest sympathy and our columns have always been open for the recording of scientific results. There is no department of pathological research in which we and all our readers take a deeper interest than in the study of cancer; there is no branch of medical practice in which some great advance would be so welcome as in the treatment of cancer; and the impulse which gave birth to the scheme now before us has our deepest sympathy. But as we read the "scheme" which has now been promulgated by the two Royal Colleges we feel that it falls somewhat short of what we should have expected from such a source. To the rich man to whom the appeal for money is now made we would say, "It is vastly easier to give princely sums than to solve nature's problems." To the organisers of this investigation and the draughtsmen of the scheme we would say, "The work will be done by the scientific investigator, the patient toiler in laboratory or hospital ward, and not by any committee, consultative, advisory, or executive." The scheme before us appears to have been drawn up in forgetfulness of these truisms. There are to be two committees—the general committee and the executive committee. Of what service the general committee is to be to a very difficult scientific investigation it is impossible to imagine. We notice, too, that the executive committee, which is to have the real control of the fund and therefore of the work to be undertaken, is partly composed of *ex-officio* members and it is no secret that those *ex-officio* members may not be in any way specially qualified to assume this responsibility. It seems to us that those who drew up this scheme have devoted too much thought to the construction of the committees—the flies on the wheel—and too little thought to the scientific investigators. Yet any one who sits down and thinks the matter out must see at once that cancer remains a mystery, not for lack of a committee, or of any grand scheme of collective investigation, or of big volumes of statistical, dietetic, and topographical information, but from lack of scientific observation and knowledge gained by highly-trained workers. To solve the problem of cancer the real difficulty lies in getting the right workers, not in getting the right sum of money. How are they to be got? By wide scientific training in properly equipped laboratories. The question therefore naturally arises whether, if large sums of money are forthcoming for this work, they will not be more wisely spent in securing the highest possible training of suitable men in the most perfect methods of scientific research of all kinds than in continuing work along the narrow lines at present pursued. We have the fullest sympathy with the suggestions to subsidise individual workers; we should like to see all such men not only provided with due means for carrying out their investigations but also set free to devote their entire energies to the work in hand. Only too often in this country important scientific researches have to be made in the short hours than can be snatched after the pressing claims of a practice have been met and they are liable to grievous interruptions. It should be the ambition of the rich to bear their share in scientific progress by enabling such workers to devote their best energies to their highest call.

We notice that the first object of this fund is "to provide, extend, equip, and maintain laboratories to be devoted *exclusively* to cancer research" (the italics are ours). If we knew that that malignant disease was something quite distinct from every other morbid process in the human body there might be some justification for this "exclusiveness." But in default of this knowledge it seems to us unwise thus to limit the purview of those supported by this fund. None can tell from what direction the great discovery will come—from physics, chemistry, or biology in its widest sense. It is, indeed, very probable that he who looks only at cancer will fail to "see" it. While, therefore, we feel in every way desirous that further and clearer light may be thrown on the mystery of malignancy, and to that end most heartily join in the appeal to the wealthy of the land to furnish the needed funds, we think that the scheme as formulated needs very careful reconsideration. The problem is a very difficult one to solve; no cut-and-dried committee scheme is likely to be successful. Any scheme of collective investigation is illusory. Rather do we need to stimulate new methods of inquiry and the consideration of the question from a wider scientific standpoint.

◆

Thoracic Phthisis: The Lumleian Lectures.

THE "Lumleian Lecture in Surgery" was founded in the year 1581 and in the annals of the Royal College of Physicians of London it is referred to as the "Chirurgical Lecture." A very ambitious scheme of surgical lectures was at first adopted, an account of which may be found in HOLINSHED ("Chronicles," vol. iii., p. 1349), but it soon ceased to be either practicable or required and the present lectures were substituted. The subject chosen by the Lumleian Lecturer for his discourses has generally been interesting from a clinical point of view, and Dr. FREDERICK T. ROBERTS in taking as his theme the Comprehensive Study of Thoracic Phthisis has accurately followed precedent and has furnished a valuable monograph which contains a vast amount of information culled from clinical experience. At first sight his title is disappointing. Within recent years the term "phthisis" has been gradually dropped by many leading authorities, the term "tuberculosis" with a qualifying adjective, especially "pulmonary," being employed in its stead. It would appear on a cursory glance, therefore, that Dr. ROBERTS is making use of a word which we had hoped was becoming obsolete, more particularly when applied to "pulmonary tuberculosis." Dr. ROBERTS, however, early in his lectures makes it perfectly clear that such is not the case. He explains that he employs the expression "thoracic phthisis" advisedly to emphasise two most important practical facts. First, in the cases of chest disease usually grouped as "consumptive" the morbid changes are by no means limited to the lungs but in the large majority of instances other thoracic structures are more or less affected as well and the mischief may even originate in certain of these structures. Secondly, even assuming the disease to be essentially a manifestation of tuberculosis, other lesions and pathological changes may be associated with the tuberculous mischief from the first or from an early period, while they are certain to develop or to supervene in various combinations and degrees during the progress of cases which are at all prolonged and especially in those of a markedly chronic type. Ultimately the conditions not uncommonly become extremely complicated. In other words, "thoracic phthisis" and "pulmonary tuberculosis" are by no means synonymous terms—a fact which, we admit, is sometimes entirely ignored or forgotten. Unfortunately, there is very generally a tendency to forget the hackneyed, but nevertheless true, phrase, "Tota ars medici est in observationibus," and, having discovered "crepitations" at one "apex," to designate at once the case as one of "consumption" and forthwith to advise "open air," or some other form of treatment, without paying due attention to the need of searching for other lesions. Dr. ROBERTS'S lectures are throughout a protest against any mere narrow perception of tuberculous disease of the thorax and its contents. We thoroughly endorse the lecturer's words when he says that, having adequately mastered the subject in the abstract and gained a fairly intelligent and definite knowledge of facts and not of mere theories, assumptions, or doctrines, and having acquired adequate skill in clinical investigation, the trained practitioner must regard it as his imperative and unfailing duty to deal with every individual case which comes under his care from a comprehensive standpoint—namely, to study it systematically and thoroughly, so as to be in a position to give rational and trustworthy advice, to do the best that is possible for this unfortunate class of patients, and to take suitable and adequate measures of a prophylactic or preventive nature as far as circumstances permit. The experience gained in the sanatoriums for the treatment of tuberculosis which already exist in this country bears witness to the want of care exercised in the selection of cases which are sent to such institutions. Doubtless the fault lies partly with the patients themselves, who are either unable, or perhaps unwilling, to perceive that their condition is such as cannot obtain benefit from treatment that would be suitable for cases in an earlier or less complicated stage of the disease. In some instances, however, the error lies on the part of the practitioner who may be inadequately acquainted with the principles of sanatorium treatment and the class of case most likely to benefit by it. The comprehensive view taken by Dr. ROBERTS of "thoracic phthisis" will, if carefully studied and followed, have a valuable effect in preventing such mistakes and a double benefit will follow. Disappointment, discomfort, and distress will be prevented in the case of a large number of patients and their friends, and results which tend to bring into disrepute a valuable therapeutic measure will be obviated.

There are many points raised by Dr. ROBERTS in these lectures to which reference might be made, but we must be content with noticing a few of those which concern not only individual patients but the general population. The mode of spread of the disease is most important to the medical profession. The idea that pulmonary tuberculosis is infectious has naturally created the greatest alarm amongst the community at large and extreme measures have been proposed to check the contagion. We join with Dr. ROBERTS in his protest against the modern tendency to regard all questions relating to tuberculosis too exclusively from the scientific side and to accept no doctrine or opinion as trustworthy or authoritative unless it emanates from a pathological or bacteriological laboratory. Scientific investigation does not cover the whole field and tuberculosis as it is seen in actual practice must be dealt with and studied on a much broader basis and from other standpoints. Pulmonary tuberculosis is, unfortunately, one of the most common of diseases. It may undoubtedly be communicated from one person to another, but the laity must be given to understand that it is not infectious in the same manner that scarlet fever is. There are some authorities who would have pulmonary tuberculosis added to the list of compulsorily notifiable diseases. We believe that the general enforcement of such a proceeding would have disastrous results on our social system and that commercial, professional, social, and practical life would be materially interfered with. We agree with Dr. ROBERTS, therefore, that it is our business as a profession at once to endeavour to allay this excessive and unreasoning alarm and to make the laity understand that with very simple precautions there need be little or no fear of infection. If the public is taught the danger of indiscriminate expectoration, especially in public places and vehicles, no legislative measures will be immediately necessary. The risk of communicating the disease is, of course, greatest where many people are gathered together. In this connexion Dr. ROBERTS gives publicity to a statement that no arrangements are made in post-offices in this country as regards expectoration, while in addition their want of ventilation and other sanitary defects are but too evident. We believe that in this instance he has been wrongly informed and that the necessary hygienic precautions are enforced by the postal medical offices.

In conclusion, we wish to congratulate Dr. ROBERTS on the essentially practical manner in which he has brought before the profession a most valuable and instructive discourse.

Deafness and Ear Disease in School Children.

THE Otological Society of the United Kingdom has rendered a service to national education and to the community. It has drawn attention to facts which are startling, and which cannot be lightly passed over by those responsible for the training and future well-being of the children of the poor. The facts are embodied in a report by Mr. ARTHUR H. CHEATLE on the Examination of the Ears of 1000 School Children, which formed the subject for discussion at a meeting of the society on Monday last, and a report of which will be found at p 1111 of our present issue The children examined were those of the Hanwell District School which receives the children of the poorest class from Southwark and the City of London. The school includes an ophthalmic department into which children suffering from diseases of the eye, especially ophthalmia, are received from all the metropolitan Poor-law schools. The object with which the investigation was undertaken was to ascertain what proportion of children suffer from deafness and diseases of the ear in order that attention, if necessary, might be drawn to the subject. In conducting such an investigation Mr. CHEATLE was confronted with a difficulty at the outset—namely, the want of a trustworthy, and if possible a standard, test of hearing in children. The test employed was that of putting simple questions in a quiet whisper at an arbitrary distance—which in this case was 18 feet. At first the children had both ears unclosed and the eyes shut; afterwards one ear was unclosed and turned to the speaker and then the other. The test was found to form a good working standard. Other precautions, such as tuning-fork tests, were applied when necessary and in all the cases of middle-ear disease inflation was employed in order that the diagnosis might be strengthened by the improvement obtained. After the hearing power had been noted the ears, the nose, and the pharynx, and in a large number of cases the naso-pharynx, were examined. The results of these examinations were classified in the report, an additional table being introduced to permit of comparison of results of the examinations made in the main school with those obtained in the ophthalmic school. On the whole the results obtained in the two schools corresponded. The feature of the report with which the medical profession as a whole is more particularly concerned is that out of 1000 school children the ears were found to be normal in only 432; of the remainder the external ear was found to be affected in 49, the middle ear in 518, and the internal ear in one. The hearing power was more or less defective in 520. In many of these children the defect had been unnoticed by the teachers. To quote Mr CHEATLE's words, "there is no disregarding the fact that the report is a startling one." Moreover, it appears from the discussion which followed that the statistics of the Hanwell school agree in important respects with those derived from a similar investigation conducted in Liverpool Before drawing any general conclusion from these statistics it is important to bear in mind that the figures upon which they are based are comparatively small and that the children who were dealt with were in both cases drawn from the poorest classes, living in insanitary surroundings and under conditions conducive to adenoid hypertrophy—which appears to have been present in 434 of the 1000 children examined at Hanwell. If we do not allow for these special considerations we may arrive at an unduly pessimistic conclusion; and, as was pointed out in the debate, it would be of interest for purposes of comparison to have statistics of an investigation conducted amongst children of the better classes who have always lived under fairer conditions. The whole matter is one that, now that it has been broached, should be thoroughly taken in hand by the medical profession. Mr. CHEATLE's report states that in the majority of the large cities in Germany physicians are appointed to the schools to examine the eyes and ears of the scholars. In the canton of Zürich according to the official school report for the years 1899 and 1900, 108,297 children were medically examined and the ears were found to be in some way affected in 117 per 1000 In Stockholm in 1901 two aural surgeons were appointed by the town government to examine all the poor school children The schoolmasters in the Swedish capital call on the parents of those affected to inform them of the necessity for treatment. From the economic aspect it would be difficult to mention a social grievance upon which the light of preventive medicine could be more profitably shed. The Otological Society of the United Kingdom has wisely appointed a committee from amongst its members further to investigate the matter—let us hope with a view of submitting some adequate scheme to the Board of Education These investigators will, we think, find that their organised efforts will meet with the approval and support of their professional colleagues.

THE Religious Tract Society will publish on May 1st a Life of James Chalmers, the great New Guinea missionary It has been prepared by the Rev. Richard Lovett, M A., to whom the family of the late James Chalmers have entrusted the whole of the letters, memoranda, and reports in their possession, including an autobiography from the pen of James Chalmers himself. This has been incorporated into the Life

Annotations.

"Ne quid nimis."

MEDICAL EDUCATION.

THE differences with regard to the control of the preliminary scientific education of the medical student which exist between the General Medical Council and the English Royal Colleges have been brought into recent public notice by an article in the *Times* of April 4th and by a letter from the President of the Royal College of Surgeons of England on April 11th. We published the debate on the subject in the General Medical Council on June 15th, 1901, and we expressed our opinion on the matter in our next number. The question, which has been for some years past, and is still, in dispute, is concerned with the recognition of schools for the teaching of the preliminary sciences—chemistry, physics, and biology. The authorities of the two Royal Colleges, knowing that there were many excellent science schools in Great Britain, as shown by the preliminary scientific and intermediate B.Sc. examinations of the University of London, which were quite open to anyone without any special bearing on medical studies, compiled a list of institutions from which they would receive certificates. Six months were allotted for chemistry, physics, and practical chemistry, and twelve for the same sciences with biology. An examination in these subjects was then passed under the control of the Conjoint Board of the two Royal Colleges, and this curriculum was only permitted in the case of those who had previously passed a recognised examination in Arts. In order to ascertain the science schools which were properly equipped with teachers and laboratories the Government grant list of the Science and Art Department was first taken into consideration, whilst others were personally inspected by the licensing authorities, as is now done in all cases. As the General Medical Council in July, 1890, extended the medical course to five years, providing that the first year might be passed at a university or teaching institution, the Colleges at once recognised the teaching at the science schools as a first year's course. The personal inspection of the schools has steadily been improved and many of them have been removed from the list, whilst others are frequently added to it. In November, 1898, the Royal College of Surgeons in Ireland made a formal complaint to the General Medical Council of this plan of procedure, alleging that it reduced the period of time in the case of the students affected to four years. It further stated that many of the schools were non-medical, "being either grammar schools or departments of local technical schools, the teaching of which may be open to question." It is most important to notice that these schools had been inspected by the Conjoint Board, whilst the General Medical Council had never visited them. The Council on the recommendation of the Executive Committee passed a resolution that no student should be registered until he had passed a preliminary examination as required by the General Medical Council and had produced evidence that he had commenced medical study at a university or medical school or at a scientific institution recognised by one of the licensing bodies and approved by the Council. The Conjoint Board replied to this official communication that it "failed to recognise any authority under the Medical Acts in virtue of which the General Medical Council may impose the conditions formulated in the regulation in regard to the registration of medical students" and that it "declined to recognise the requirement that scientific institutions where medical study is commenced should be approved by the Council." The Council adhered to its resolution, when the two Colleges resolved "no longer to require the registration of students by the Council as a condition of admission to examination for their diplomas, and that the regulation for the qualification of the two Colleges had been altered accordingly." The Conjoint Board is undoubtedly right in pointing out that the General Medical Council has gone beyond its province in demanding that before recognising institutions for teaching science the Colleges shall see that they are approved by that Council. The "authority of the Medical Council" does not legally exist. On its constitution only advisory and inspecting powers were given to it, with power to appeal to the Privy Council in case of any licensing body which it thought had abused its privileges, and in the case of the Apothecaries Hall of Ireland the Privy Council compelled the General Medical Council to appoint examiners in surgery as the Society had previously demanded. The last-named body is scarcely likely to appeal to the Privy Council against the Conjoint Board in November when there will be a further discussion in the General Medical Council on the matter. The Council has acted without the support of law, and the Royal Colleges have dealt a severe blow to the excellent system of registration of medical students which was formerly in vogue, even though it be in discharge of a function and a responsibility imposed upon them by charter.

PAYING WARDS OR PAYING HOSPITALS.

A RECENT correspondence in the *Times* has revived the question of payment by hospital patients. Among the writ on the subject are two experts on hospital management namely, Sir Henry Burdett and the Hon. Sydney Holland. The former is of opinion that "the moment is therefo favourable for the consideration of the introduction of p wards to large general hospitals, especially in London." S Henry Burdett's idea is that there should be an insuran office which would for an annual premium issue policies defray the cost of hospital maintenance and treatmen including the fees of the medical attendant. The schem outlined by Sir Henry Burdett is as follows:—

> To succeed, pay wards under the administration of the managers a great voluntary hospital must be in a separate building, with entrance quite distinct and apart from the free hospital and admini tration departments. The wards, on the continental plan, should graded, so that patients may be classified, and the rates of payme fixed according to the means of each patient. All patients' paymen to be pooled, and a percentage of them set apart for the remunerati of the medical men in attendance in the pay department, and ea patient to have the right of being attended, if he so wish, by his ow doctor. So organised, a pay ward should be popular with the patien and the profession, and a source of revenue to the hospital manage If an insurance company is established on the lines I have suggeste then the managers and the medical practitioners would be guarante against loss, and everybody should be satisfied and benefited.

The Hon. Sydney Holland, on the other hand, thinks that t paying wards should not be under the same roof as the no paying wards, but that if a hospital is to receive payin patients it should be a building entirely by itself. H scheme is as follows:—

> I feel sure that a hospital properly built for paying patients could t worked to give a fair return on its capital cost, and that such a hospit would meet a really great want. It should be managed as hospital are now managed; there should be first, second, and third class accom modation, leaving patients to make their own arrangements with the own medical attendants. The charge should be inclusive of everythin and should include the payment of a resident medical officer actin under the several doctors and surgeons attending the patients.

We think that, on the whole, the Hon. Sydney Holland's ide is the better of the two. There can be no doubt that hospital as opposed to a private nursing home is a sor need. The tax which a serious and long-continued illnes lays upon a middle-class family is very great. It involve the expense of medical attendance, the expense of at leas two nurses, and an upset of household arrangements. All th in a family whose income is perhaps only some £400 o £500 per annum spells something like ruination. Agai the average London home—we can scarcely call it a house—is not constructed with any views towards convenience in sickness. The mere question of food is a difficulty, for a decent larder is generally unknown. Sickness in a flat is a still more severe ordeal, and in the case of any infectious complaint it is a danger to the community. For all these reasons, then, we should welcome the paying hospital The expenses of the private nursing home are, in many cases, prohibitive, but such institutions are run as commercial speculations and the proprietors thereof have to make a profit. No such profit would have to be made by the paying hospital.

LETTERS ON THE BREAKFAST TABLE.

IT is the custom of many households to have the morning's post, including letters, newspapers, and circulars, placed upon the breakfast table. In fact, the parlourmaid usually takes upon herself the duty of sorting the post, placing the packets according to whom they are addressed in front of the seats occupied at the breakfast table by the respective members of the household. The classification is made all the more exact in many instances, perhaps, by putting the documents on the plate, which, after they have been removed, serves for the toast or the roll and butter The plan is convenient, but from a sanitary point of view it is appalling It is undeniably a dirty practice. In nine cases out of ten the envelope containing a letter is licked, as is also the stamp, by the sender Infection, therefore, may easily lurk here, especially as by the time the letter reaches its destination the stamp and sealed cover are dry Any materies morbi present would be easily detached. Then there are the risks of infection to which a letter is exposed in transit. The sorter at the post-office or the postman may not be as bacteriologically clean as is desirable. The dust of the road may adhere to any exposed gum or the letters may be dropped, and the bacteriology of road dust exhibits some well known pathogenic organisms. Letters are frequently smeared with road mud. Amongst the microbes recognised in road-sweepings are the microbes of pus, malignant œdema, tetanus, tubercle, and septicæmia. The post probably is a very wide distributing agency of all sorts and conditions of organisms and this it would be difficult to prevent. But surely care might be taken to keep from association the plate upon which food is partaken and the letter or newspaper packet. It follows that from a hygienic point of view letters should never be opened or read during a meal Good manners, moreover, would dictate the same thing and thus be in accordance with strict hygienic observance.

LACTESCENT ASCITES AND ATROPHIC CIRRHOSIS OF THE LIVER.

AT the meeting of the Société Médicale des Hôpitaux of Paris on March 21st M A. Souques read an important paper on Lactescent Ascites and Atrophic Cirrhosis of the Liver Following M. Jousset, he would substitute the term "opalescent ascites" for those of "chylous" and "chyliform ascites," because it has the advantage of describing the fluid without implying any pathological theory of its origin. M Jousset applies the term "opalescent" to fluids of all shades of colour intermediate between milky white and colourless and the term "lactescent" to the highest degree of opalescence. Examples of opalescent ascites associated with atrophic cirrhosis of the liver are rare. M. Souques described the following case of cirrhosis of the liver with lactescent ascites A man, aged 61 years, addicted to alcohol, was admitted to hospital on Dec 26th, 1901. He had been in good health until the previous June when he began to lose appetite and strength. In August he noticed that his abdomen was enlarging He was much wasted and had an earthy complexion. There was much ascites and the collateral venous circulation was developed. He often suffered from diarrhœa. The urine contained urobilin and a little reddish brown pigment. A few days after admission œdema of the lower limbs and scrotum appeared On Jan 20th, 1902, paracentesis abdominis yielded 13 litres of lactescent fluid. On the 24th the ascites was again beginning and the urine was dark and scanty (250 grammes in 24 hours) On Feb 12th paracentesis yielded 15 litres of milky-white fluid The general condition became worse and death took place on the 16th At the necropsy 10 litres of fluid similar to that which had been removed during life were found in the peritoneal cavity The liver was atrophic and weighed 1270 grammes; scattered through it were hard yellow granulations. Microscopic examination revealed annular extra-lobular cirrhosis. Some of the hepatic cells showed fatty degeneration. The abdominal lymphatic vessels were not dilated and showed no perforation. A "pocket" was found behind the aorta and between the pillars of the diaphragm which communicated with the thoracic duct and appeared to be the receptaculum chyli It was filled with blood-clots and must have formed an obstacle to the flow of chyle. The lactescence of the ascitic fluid was not modified by centrifugalising and when allowed to stand in a tube the fluid did not separate into layers but a slight reddish deposit of red blood corpuscles formed. Microscopically the fluid showed numerous small granules and refractile vesicles which did not stain and 12,000 mononuclear leucocytes, mostly lymphocytes, to the cubic millimetre. Ether did not render the fluid clear Chemical analysis gave per litre in grammes 8 1 albumin, 0·25 fibrin, and 7·32 globulin. M. Jousset has been able to collect only 14 cases of atrophic cirrhosis of the liver with opalescent ascites. Obstruction of the thoracic duct was found in some of the cases but it is evidently only a predisposing cause. Ligature of the thoracic duct may be performed in animals without producing effusion of chyle or even dilatation of the chyle vessels. M. Souques suggests that the alcohol taken directly affects the chyle vessels at their origin and causes diapedesis of leucocytes into the peritoneal cavity already filled with ascitic fluid. There they are destroyed, giving rise to an emulsion which determines the phenomenon of opalescence.

THE STATISTICS OF 100 CASES OF ABORTION.

SINCE the days of Hippocrates, who was one of the first to express this view, some obstetric writers have been accustomed to regard an abortion as more dangerous to the mother than a full term delivery That the danger of such an accident if it be properly treated is not so great as is often supposed is shown by Dr Blondel in a paper read before the Obstetrical Society of Paris and referred to by our Paris correspondent. In this paper he records the results of 100 cases of abortion, without a single fatal case, which had occurred in his private practice during a period of 12 years. The exact mortality of cases of spontaneous abortion is difficult to ascertain, but it is probably less than that of full term confinements Even the mortality following abortion criminally procured is really quite small, and it seems certain that Tardieu, who met with 60 deaths amongst 116 cases, had quite an exceptional experience. Brouardel, for instance, mentions 72 cases of criminal abortion without a death, and amongst Dr Blondel's 100 cases 52 were certainly of such a character, and possibly 26 of the remaining cases were of the same kind. The proper treatment of a case in which there is reason to suspect that criminal measures have been used is always a difficult matter to decide in the absence of positive indications for interference, such as evidence of septic intoxication or septic infection or the retention of portions of the ovum. Dr. Blondel recommends the following plan of treatment which he pursues in all cases where there is reason to suspect that criminal intervention has taken place. The uterus is curetted with the finger and with a curette. It is then swabbed out with glycerine of creasote of a strength of 1 in 3, is douched out with tincture of iodine, and a gauze drain dipped in glycerine of ichthyol (1 in 10) is introduced. The drain is changed every two days; at the same time the uterus is flushed out with a solution of corrosive sublimate. The results obtained are certainly very good, but it is a question whether they would not have been equally good with a less energetic plan of treatment. It is to be noted that in 60 of the cases the fœtus and placenta had already been expelled from the uterus when they were first seen. The most interesting part of the paper concerns the methods by which the criminal abortion was induced. Of the 100 cases of abortion which came under Dr. Blondel's notice 52 were purposely procured. In 22 of these a midwife was the culprit and in no less than 19 instances the patients carried out various manipulations upon themselves. On 15 occasions the midwife passed a sound and on 10 occasions a gum elastic catheter was used and an injection, presumably intra-uterine, was given. According to Brouardel this is one of the commonest means employed by French midwives. Some of them, with the view of still further swindling their clients are accustomed to inject so-called "eau d'argent" or "eau d'or" in the form of coloured water for which a correspondingly larger sum has to be paid. In two cases the patients had procured abortion upon themselves, in one instance by introducing a knitting needle and in another instance a bone knitting pin into the uterus. In nearly all cases where the patient has succeeded in passing instruments of this kind into her own uterus the organ has been found to be somewhat prolapsed. It is difficult to believe that any woman can succeed in such a manœuvre unless such a condition of the uterus is present. The fact that Dr. Blondel, even in cases where there was no doubt that instrumental interference had been carried out, could detect no wound or abrasion of the cervix, sufficient to swear to as evidence, is not at all exceptional. It is only, as a rule, when the patient dies that any trace of what has been done can be found and even then great care must be exercised in the interpretation of any supposed signs of injury.

CRUELTY TO FISH.

ON Feb. 17th a fishmonger of Berwick-street, Oxford-street, was charged at Marlborough-street Police-court by the Royal Society for the Prevention of Cruelty to Animals with having caused unnecessary suffering to 700 carp. On Dec. 23rd, 1901, he had upon a stand outside his shop a glass tank, 33 inches long and 15 inches wide, containing water about seven and a half inches in depth, in which were about 700 Prussian carp from four to six inches in length. They were put into the tank early in the morning and at 10 P.M. a large number were lying dead on the bottom. The fish were brought from Holland and were sold to foreigners for 2*d.* each at Christmas time. They were not kept in water during the voyage but were packed in trays with perforated bottoms; the uppermost tray contained ice, the water from which trickled down on to the fish beneath. Counsel for the prosecution said that the present case was the first of its kind, the proceedings being taken under the Cruelty to Wild Animals in Captivity Act, passed in 1900, which defined an animal as any "bird, beast, fish, or reptile" which was not included in the Cruelty to Animals Acts of 1849 and 1854. An offence of cruelty might consist in permitting unnecessary suffering or in cruelly abusing or terrifying an animal in captivity and might be punished with a fine not exceeding £5 or imprisonment not exceeding three months. Evidence was given to the effect that the deaths were caused by suffocation and that fish required a good supply of water in order that they might obtain sufficient air for respiration. The defendant was fined £2 with £3 3*s.* costs. At the same police-court on April 9th a naturalist of Great Portland-street, W., was charged by the same society with causing unnecessary suffering to goldfish. In his shop-window there were 13 bowls containing goldfish, some of them being dead and the water being dirty. This state of matters continued for four or five days during which the place was locked up. The defendant was fined £2 with £2 4*s.* costs. It may be mentioned that a few years ago a dealer in small tortoises was fined for having an undue number packed in casks so that many died.

CONGENITAL PORENCEPHALUS LIMITED TO THE AREA OF A PARTICULAR CEREBRAL ARTERY.

WHILE the condition of porencephaly, either congenital or acquired, is not particularly rare the opportunity for full and satisfactory pathological investigation is less frequent. In the first volume of "Studies" from the Royal Victoria Hospital, Montreal, issued in January last, Dr. D. A. Shirres has published a lengthy paper on a case of Congenital Porencephalus in which the distribution of the lesion corresponded to the territory of the middle cerebral artery. The case was of special importance owing to its long duration, its characteristic mental and physical symptoms, and the facility which it afforded for tracing the course of various nerve-tracts in the brain and medulla oblongata. The patient was a woman, aged 76 years, who died from pneumonia occurring during a state of dementia. No etiological factor in connexion with the patient's nervous system could be traced except the fact that severe fright and threatened abortion affected the mother during the seventh month of pregnancy. The child was, however, carried till, and born at, full term and seemed to be a normal infant, but when a week old she manifested stiffness of the right arm and fingers. Later she appeared to be a little backward in intelligence, not walking till the third year or talking till the fourth. Owing to paresis of the right hand the patient was taught to write with the left. She never suffered from epilepsy or fits of any kind. The right foot was inclined to drag a little in walking but it did not seem to hinder progress to any extent. There was some kyphosis of the spine and the right shoulder was lower and more forward than the left. She married twice but had no children by either marriage. When she attained the age of 60 years her mental faculties began to weaken rapidly. She became very religious, obstinate, and eccentric, living by preference a hermit's existence apart from her friends. At this period she developed delusions of persecution and was somewhat demented. She contracted pneumonia and died at the age of 76 years as already stated. A distinct family history of neurasthenia and arterio-sclerosis was obtained. Thus of seven other members of the family two brothers and one sister died from apoplexy and one brother had an apoplectic stroke but was still alive though nervous and mentally enfeebled. The necropsy revealed the following lesions. Upon opening the dura mater of the skull a remarkable and extensive condition of porencephaly was recognisable in the left cerebral hemisphere. The area of destruction was of a sausage-like shape extending around the Sylvian fissure into the temporo-occipital region and involving evidently the centres of speech, the face, and the upper extremity, the brain substance being replaced by a membrane distended with clear fluid. The left cerebral hemisphere weighed 302 grammes, while the right weighed 560 grammes, but the right half of the cerebellum was markedly smaller than the left. The right hemisphere was normally and richly convoluted, whereas in the left hemisphere the convolutions were "very poorly developed though not simplified." Dr. Shirres regarded the condition as due to an occlusion (thrombosis) of the middle cerebral artery outside the origin of the perforating arteries for the basal ganglia. "The lesion had apparently occurred in the later months of fœtal existence and was due to rupture of fœtal vessels in the placenta." The corpus callosum appeared to be normal in size and the corpora striata were equal. There were general atrophy of the left optic thalamus both as regards the cell-bodies and nerve-fibres of its various portions, and marked atrophy of the posterior limb of the internal capsule, corpora quadrigemina, and optic tract on the left side. Bundles of degenerated pyramidal fibres could be traced through the left cerebral peduncle and the fronto-cerebellar and occipito-temporo-cerebellar bundles were degenerated in the same situation and in the pons. Other degenerations were found in the fillet and in several of the nuclei throughout the left half of the pons. The nuclei of cranial nerves in the floor of the fourth ventricle were normal.

THE MEDICO-LEGAL SOCIETY.

AS we announced in THE LANCET of April 5th would be the case, a general meeting of the newly formed Medico-Legal Society was held on April 10th at 20, Hanover-square, London, W. The usual rules for the conduct of a society were adopted and the following officers were elected: President: Dr. W. J. Collins, L.C.C., barrister-at-law. Vice-Presidents: Dr. M. Hay, Professor of Medical Jurisprudence in the University of Aberdeen; Dr. A. Bostock Hill, Professor of Medical Jurisprudence in the University of Birmingham; Mr. A. J. Pepper; Dr. G. Danford Thomas, Coroner for London and Middlesex. Council: Mr. S. B. Atkinson, M.A., B.Sc., barrister-at-law; Dr. C. O. Hawthorne; Dr. T. N. Kelynack; Dr. H. Harvey Littlejohn, Lecturer on Medical Jurisprudence in the University of Edinburgh; Dr. J. S. Risien Russell, Professor of Medical Jurisprudence in University College, London; Dr. F. J. Smith, Lecturer on Medical Jurisprudence at the London Hospital; Dr. W. R. Smith, Professor of Medical Jurisprudence at King's College, London; Dr. F. J. Wethered, Lecturer on Medical Jurisprudence at the Middlesex Hospital; and Dr. H. W. Williams. Honorary treasurer: Dr. W. Wynn Westcott, coroner for North-east London. Honorary secretaries: Dr. W. McCallin, barrister-at-law; and Mr. R. Henslowe Wellington. The object of the society is to advance the knowledge of medico-legal matters.

THE HEALTH OF THE CITY OF LONDON.

THE monthly report of the medical officer of health of the City of London for the four weeks ending March 15th affords some interesting reading. In the four weeks there were registered 97 deaths but 52 of these occurred in St. Bartholomew's Hospital. There were 34 cases of infectious disease notified, of which 10 were cases of chicken-pox. Six cases of small-pox were notified but two of these were subsequently proved not to be small-pox. To come to the smoke nuisance, 552 observations were made and intimation notices were served upon the owners or occupiers of the Bucklersbury Restaurant and the *Daily Telegraph* printing works. A list of places is given where notices have been served and where in the majority of cases improvement has been effected. Some cases, however, are marked with an asterisk, owing to the nuisance still existing. These are nearly all taverns or restaurants. Certainly, in our experience the chief offenders against the smoke enactments, apart from factories and electric-light works, are restaurants and bakeries. With regard to adulteration milk is still the article most extensively adulterated, or perhaps we should say sold fraudulently. Nothing is added except water but in many cases fat is abstracted. There were 12 prosecutions under the Food and Drugs Acts, mainly concerned with milk, while under the Public Health Act of 1901 six persons were prosecuted, chiefly for dealing in diseased meat. One scoundrel, a farmer, was fined £80 for depositing four quarters of diseased beef for sale. His name is Samuel Egar and he lives at Thorney, Peterborough.

THE ANTI-VACCINATIONIST IN HIS TRUE COLOURS.

IN THE LANCET of April 12th, p. 1074, under the above heading, we commented upon the statements of a person named W. D. Stokes. Mr. Stokes told many untruths, but then he is ignorant and probably believed that what he said was true. The following paragraph appeared on the second column of the third page of the *Morning Leader* of Tuesday, April 15th. It is an editorial paragraph and the editor of the *Morning Leader* is an educated man. Yet he can publish such stuff as this.—

AFTER VACCINATION.

ANOTHER LITTLE GIRL DIES A PAINFUL DEATH.

> Particulars are to hand of another particularly distressing fatality arising presumably through vaccination, and the circumstances of which bear a very close resemblance to the case of the little girl Harriet Stow, which was inquired into by Dr. Wynn Westcott, at Hackney, as reported in the *Morning Leader* of Jan. 30th. The deceased was Nellie Cooksey, aged seven years, the youngest child of a brass finisher, residing at 86, Waldon New road, Croydon, and in consequence of the notices issued by the school authorities she was subjected to vaccination, the operation being performed by Dr Adams, jun., at the surgery of his father, who is public vaccinator for Croydon. A week afterwards the child was examined by Dr. Adams, sen. On the eleventh day, however, the child became very ill, and during the succeeding night she was seized with a fit. The following day Dr. Neligan was called in, and he pronounced the patient to be in a serious condition. She lost the use of her limbs, the mouth became fixed, and the brain appeared to be paralysed. She expired exactly 14 days after the operation had been carried out. Prior to this the deceased was quite well and strong, and she had not had any illness for four years. The symptoms—as described—were quite consistent with lockjaw and in trying to force the mouth of the little sufferer open a tooth was broken, yet the causes as notified on the certificate were "Pneumonia and heart failure."

True it is that "a lie which is half the truth is ever the basest of lies." It is true that the child died after vaccination. Numbers of people have died after vaccination, so no doubt have numbers of people died after reading the *Morning Leader*. Why does the *Morning Leader* say that the fatality arose "presumably through vaccination"? and what does it mean by saying the "symptoms—as described—were quite consistent with lockjaw"? In lockjaw or tetanus the brain is not paralysed, but severe nervous symptoms are quite common with pneumonia, especially in children. Surely Dr. T. R. Adams and Dr. J. W. Neligan are more likely to know what was the matter with the child than is the editor of the *Morning Leader*. We can respect the honest, though mistaken, anti-vaccinationist, but it is prostituting the press to make it the medium of circulating deceitful paragraphs such as the one which we have quoted.

DEMENTIA PRÆCOX.

CONSIDERABLE attention has been given during the last few years to a group of mental disorders belonging to the adolescent period of life and designated "dementia præcox," a description of which was given in these columns two years ago.[1] In a recent *Thèse de Paris* (1902) Dr. René Masselon deals with the subject in its latest developments and carries the classification of the various mental disorders of this group a step further. Four forms of dementia præcox are recognised—viz., a simple, a hebephrenic, a katatonic, and a paranoid form. Simple dementia præcox is marked by a slow and progressive mental enfeeblement beginning during adolescence and pursuing its even course without the development of delusions. The hebephrenic or delusional form is characterised by a medley of states of mental excitement, depression, hallucinations, and mental confusion. The delusions are never systematised. The vesanic manifestations are mobile and the temper and humour of the patient are variable. The katatonic form is marked by phases of stupor and negativism—i.e., of passive resistance to enforced movements and acts, cataleptoid and stereotyped attitudes, postures, and marked responsiveness to suggestion The clinical group of symptoms of the latter class was long ago described by Kahlbaum under the general name of katatonia. The paranoid form is marked by rapid intellectual enfeeblement with sensorial disturbances and delusive conceptions evolved in an atmosphere of apparent mental lucidity. Among the somatic disturbances attending dementia præcox there may be exaggeration of the knee-jerks, pupillary anomalies (mydriasis with sluggish reflexes), vaso-motor feebleness and instability, secretory disturbances, and occasionally fits of convulsive character, marked by much histrionic and hysterical movement. Dr. Masselon gives the detailed clinical histories and minutiæ of 13 patients personally observed, of whom five were males and eight were females. The ages at the onset of the mental disease were as follows. In three single women the ages were 17, 17, and 21 years, in five married women the ages were 26, 26, 27, 29, and 35 years, and in five males the ages were 16, 17, 18, 22, and 23 years. The faculty of voluntary attention was lost in all cases and the will was enfeebled, or, in the severer cases, entirely abolished. Apathy and an almost entire absence of curiosity were observed, while bizarre attitudes, echolalia, and motor *tics* were common. As regards curability it was found from the study of a large number of cases and observations collected from the literature of the subject that 8 per cent. of the hebephrenic and 13 per cent. of the katatonic patients recovered. It is possible that a fifth form of dementia præcox may yet have to be added to the above four enunciated by Dr. Masselon—viz., a form of dementia præcox in which loss of inhibition or self-control and a predominance of dangerous and destructive impulses and instincts are among the most notable features which appear, soon to be followed, however, by mental enfeeblement and unmistakeable signs of insanity. Cases of this sort developing during adolescence are not unknown to psychiatric literature though but little studied hitherto. They are not to be confounded with the so-called cases of moral imbecility in which the malady has an earlier origin and pursues a different course.

---

[1] THE LANCET, Feb. 10th, 1900, p. 337.

THE "CURE" OF INTEMPERANCE.

IT must be reckoned as a fact of hopeful augury when a disease or a disorder is chosen as the battle-ground of rival "cures." The habit of intemperance, though not in the strict sense a disease, resembles one in this particular. It has given rise to a variety of systems of reform. Nostrums innumerable have been levelled at it. Like all others of their class they promise perfection and even profess to have realised it but they do not furnish the proofs of even moderate success. As might be expected the secret which they profess to have discovered is guarded with all the jealousy of a trade patent. Nothing is given away to humanity. The miracle will be performed but the entertainment must be paid for. This is, in brief, the usual history of these so-called cures. They are merely appeals to faith—and to credulity. To this fact they owe any slight value which they may possess, for there is no drug known or discoverable which can obliterate a moral propensity. It does not follow, however, that the drinking habit or even the condition of alcoholism is intractable. The mere existence of so many "infallible" remedies is one evidence that mankind as a whole does not despair of the drunkard's reformation. Wherever his enslaved will can be aroused to an effort for freedom and can be sustained in the effort there is a reasonable hope that it will succeed in its endeavour. This fact, not the use of any drug—except, of course, where this may be required to combat a physical malady—indicates the true line of treatment. Any system in order to be successful must include the removal of the source of temptation or of the individual from it, the stimulation of his interest in some wholesome pursuit, his regular occupation in it, and a plain and sufficient diet strictly moderate in respect of meat and free from substances known to excite thirst. It is on these principles that the recently established inebriate homes are conducted. If only they were generally remembered and acted on in private life by the relatives and friends of the intemperate a genuine cure would be more common than it is.

THE DISTRIBUTION OF PLAGUE.

DURING the week ending April 6th 13 cases and 9 deaths from plague have been reported throughout Egypt. 2 cases and 2 deaths, 1 of which took place out of hospital, were reported from Kom el Noor; 7 cases and 5 deaths, 1 out of hospital, from Deshneh; 3 cases and 2 deaths, 1 out of hospital, from Ezbehs near Benha; and 1 case from Sheblanga. As regards the Mauritius a telegram from the Governor received at the Colonial Office on April 11th states that for the week ending April 10th there were three cases of plague and three deaths.

GYNÆCOLOGISTS AND THE CORONATION.

A REFERENCE to our advertisement columns will show that it is proposed to hold during the Coronation week a reunion of the gynæcologists and obstetricians of the Empire. The date of the reunion is June 24th, and there will be a reception at 20, Hanover-square, London, W., and a dinner in the evening at the Whitehall Rooms, Hotel Metropole. Sir John Williams, Bart., is the President, and the invitations are issued by him, by the President of the Obstetrical Society of London (Dr. Peter Horrocks), and by the President of the British Gynæcological Society (Dr. J. Halliday Croom). Applications for tickets and information should be made to Dr. T. W. Eden, 26, Queen Anne-street, Cavendish-square, London, W.

PENTOSURIA.

IN the *Deutsche Medicinische Wochenschrift* of April 10th Dr. Manfred Bial of Kissingen describes a chemical reaction for pentosuria which is more rapid and convenient than those at present in use. The disease, he says, is not very common but is nevertheless of clinical interest because in it the urine gives the ordinary reactions of diabetes although no glucose is present. The commonly employed reaction for pentosuria is that devised by Salkowski and Blumenthal and consists in boiling the urine for about half a minute with fuming hydrochloric acid and orcin; a green substance is thereby formed which can be separated by shaking with amyl alcohol and shows a characteristic absorption band under the spectroscope. This method succeeds well in the laboratory but in the consulting-room it is inconvenient on account of the acrid vapours of the acid and the tendency to percussive ebullition. Dr. Bial's reagent for pentosuria is a solution of a gramme or one and a half grammes of orcin in 500 grammes of fuming hydrochloric acid to which 25 or 30 drops of a 10 per cent. solution of perchloride of iron are added with careful trial on a test sample. Four or five cubic centimetres of this reagent and two or three cubic centimetres of the suspected urine are poured into a test tube which is plugged with cotton wool and held over a flame until the first bubbles of steam rise. If the cases is one of pentosuria a green substance either forms abundantly in thick flocks or, in the event of the proportion of pentose being small, the liquid becomes of a fine green colour in 15 or 20 seconds as it cools. If the process be conducted in a somewhat different way—namely, with two or three cubic centimetres of urine, as much orcin as will lie on the point of a knife, four or five cubic centimetres of fuming hydrochloric acid, and one or two drops of a 10 per cent. solution of perchloride of iron, boiled together for two or three minutes, the compounds of glycuronic acid, even in normal urine, are acted on and a green colour is produced, but it is quite easy to avoid confusing the two reactions. The distinction between pentosuria and diabetes is of importance to the patient because of the dietetic restrictions and the difficulties in life assurance which diabetes involves.

THE USE OF BORAX AND BORIC ACID AS FOOD PRESERVATIVES.

Professor Victor C Vaughan and Mr. W H. Veenboer of Michigan University have published in *American Medicine* of March 15th last the results of an elaborate research on the use of borax and boric acid as food preservatives with especial reference to their use in meat, bacon, cream, milk, and butter In a previous communication on Cases of Boric Acid Poisoning by Dr J F Rinehart, an account of which has already appeared in these columns,[1] it was shown that mental dulness and apathy might in some cases follow upon the ingestion of borax or boric acid if the proportion of the drug was at all considerable, when taken internally by the mouth or when applied to some absorbent surface within the body In 1900 Professor Oscar Liebreich of Berlin showed that boric acid was harmless when given in small quantity—three grains daily—to a dog and that the same applied to borax He also showed that borax and boric acid could be used for preserving fresh foods but could not be used to restore decomposed foods to a fresh state because they were not disinfectants but only feeble antiseptics The committee appointed by the Local Government Board in 1899 to investigate the use of preservatives and colouring matters in food stated in 1901 that meat and bacon exported from America into England and butter sent from Australia, America, and France contained boric acid Among the recommendations of the committee were the following: that the only preservative which it shall be lawful to use in cream shall be boric acid or borax to the extent of ¼ per cent. and that in butter or margarine the quantity shall not exceed ½ per cent. Professor Vaughan and Mr Veenboer estimated the relative degrees of bacterial growth in finely chopped meat and bacon, cream, and butter treated with varying quantities of boric acid up to 1 per cent. and exposed to the air for a variable number of days Finely chopped meat was mingled with boric acid solution and exposed for three days out of doors at a temperature slightly below freezing-point and then was placed indoors at a temperature varying from 15° to 25° C Loop-cultures were made at intervals from the mixture on gelatin and agar agar plates and the number and rate of bacterial growths were estimated. The results showed that while quite small quantities of boric acid served to preserve the meat the growth of bacteria was not entirely prevented. Similar but more marked results in the number and rate of bacterial growths were obtained with cream. In butter and margarine the growths were slower and less in number "We observed in our experiments that meat without boric acid when kept at ordinary temperatures became 'slimy' within a few days From the surface of such meats we made gelatin and agar plate-cultures and from these we obtained 20 different kinds of micro-organisms. Of these 14 were [species of] peptonising bacteria, and all of these 14 were aerobes.' The sprinkling of boric acid on hams, bacon, and meat prevented the growth of these bacteria and kept the flesh from getting slimy The following conclusions were drawn: 1. The use of borax or boric acid as a preservative in butter and cream in the quantities stated in the report of the English committee was justified by practical results and by scientific experiment. 2. The dusting of the surfaces of hams and bacon with borax or boric acid not exceeding 1½ per cent. of the weight of the meat was effective from a sanitary standpoint. 3. Meat thus treated was prevented from becoming slimy

THE PREVALENCE OF SMALL-POX.

THE returns of small pox in London for the past week show the following figures. On Saturday, April 12th, 29 fresh cases were notified and removed; on Sunday, the 13th, there were 19 fresh cases, on Monday, the 14th, there were 37 fresh cases; on Tuesday, the 15th, there were 44 fresh cases, and on Wednesday, the 16th, there were 59 fresh cases. In the county of Essex for the week ending April 12th there were notified 76 cases, but this number includes all occurring in the Chingford district since Jan 1st, for, says the report from which we quote the figures, "in consequence of a *change of medical officers of health the returns of cases of* small pox from that urban district have not hitherto been received." In all, from Jan. 1st 782 cases have been reported throughout the county

THE BETTERMENT OF LONDON ASSOCIATION AND STREET NOISES

WITH the return of the flat-racing season the "winner" yeller wakes up from his winter sleep and howls in the manner in which Scottish divines of the sixteenth century described the fiends and their victims in hell as doing We have done our best to awaken the varied authorities which nominally govern London to a sense of their duties but little has been done so far The London County Council passed a by-law after bitter opposition from Professor Stuart and those who think with him. It has not had much effect because the magistrates are so very unwilling to grant relief, with the honourable exception of Mr Plowden who will convict newspaper hawkers on the complaint of a constable alone. We are glad to see that an association, calling itself "The Betterment of London Association,' has been formed which is going to agitate for a variety of improvements which, if carried out, will certainly make London cleaner, healthier, and quieter Among the matters with which the association will concern itself are the employment of children under 10 years of age in the streets, street hawkers and musicians, and the perpetual digging up of the streets by gas companies and others These nuisances are quite enough to begin with, although there are plenty of others. The London County Council does admirable work from a health point of view If it would do something to make London quieter there would not be so much grumbling at the perpetually rising rates Perhaps if the Betterment of London Association were to worry county councillors, borough councillors, and the London Members of Parliament something might be done. Any way we wish the association all success.

AT the last meeting *of the British Association* a *special* committee, with Professor C. S Sherrington as chairman, was appointed to consider the conditions of health essential to carrying on the work of instruction in schools The committee now is collecting information, and communications from medical men bearing upon the subject will be gratefully received by Mr White Wallis at 72, Margaret-street, W, the office of the Sanitary Institute

BY the munificence of Professor William Whitla of Belfast the Ulster Medical Society will soon be in fine building specially erected for its accommodation and destined no doubt to have an important effect in bringing together members of the medical profession in the North of Ireland. We trust that the society will have a prosperous existence in its new home.

---

[1] THE LANCET, Nov 30th 1901, p. 1514

A STATUE of Cecil Rhodes executed by Mr. John Tweed, the sculptor mentioned in Cecil Rhodes's famous will, is to be published immediately in a bronze 18 inches high. Full particulars may be obtained of Carfax and Co., Limited, 17, Ryder-street, St. James's, S.W., where a cast of the statue, a most vigorous and striking piece of work, may be inspected.

AN urgent appeal by University College, London, for over £1,000,000 has been brought before the public during the week by Lord Reay, President of the College. A Special Appeal Committee, including many influential names, has been formed and a public meeting has been arranged to take place at the Mansion House at a near date.

A FESTIVAL dinner to celebrate the sixty-sixth anniversary of St. Mark's Hospital, City-road, E.C., will take place on Thursday, April 24th, at the Whitehall Rooms of the Hôtel Métropole, London, at 7.30 P.M. The Right Hon. the Lord Mayor, Sir Joseph Dimsdale, M.P., will preside.

INTERNATIONAL CONFERENCE OF MEDICAL PRESS ASSOCIATIONS.

(FROM OUR SPECIAL COMMISSIONER.)

THE International Congress of the Medical Press which met in Paris from July 26th to 28th, 1900, was to have been followed by a succession of congresses destined to unite the medical press throughout the world. This scheme, however, was as vast as it was vague. The object of such a union was subject to varying and to contradictory interpretations. This was shown in the accounts which we published of the congress.[1] Indeed, so great were the difficulties that it was decided that the second congress should be preceded by a meeting of delegates. The medical press associations of various countries were each to appoint two or three delegates who would prepare a scheme to submit to the second congress for general discussion and adoption. This second congress was to have met in Brussels last year and it was intended that the delegates should have assembled in conference two or three days before the congress. But, as already explained in these columns, the multifarious correspondence in regard to the Brussels conference and congress gave evidence of such diversity of opinions that these proposals had to be abandoned for the time being. At one time it seemed as if the Paris congress would bear no fruit and that nothing further would be attempted. It was at this critical moment that the intervention of the Prince of Monaco saved the situation. There exists in the principality a medical society which in itself is a sort of international association, for the practitioners who reside at Monaco belong to many different nationalities. The president, Dr. V. Godineau, is a Belgian; the vice-president, Dr. R. Pryce Mitchell, is an Englishman; the general secretary, Dr. H. Guimbail, is a Frenchman; and among the other members there are Italian, Swiss, German, and Austrian practitioners. This society was aware that Prince Albert I. was most anxious to encourage scientific research and would like to see his principality become a neutral meeting-ground for all who sought to promote the cause of peace and scientific progress. Already an International Maritime Congress had met at Monaco. The medical society, and notably the general secretary, Dr. Guimbail, suggested that the representatives of the medical press associations should be invited to the principality, and this proposal was in complete harmony with the desire of the Prince. His Highness at once offered every hospitality and placed the Oceanographic Museum, which he is constructing, at the disposal of his guests. A tempting programme of entertainments was prepared and so many facilities were offered that the difficulties which stood in the way of the meeting at Brussels seemed to melt away like the winter snows on the sunlit shores of the Mediterranean. The permanent bureau or committee of the International Medical Press Association, which has its headquarters at Paris, and its general secretary, Dr. R. Blondel, actively seconded these proposals. It was finally decided that the international conference of the delegates of the medical press associations should be invited to meet at Monaco on April 7th. The object was to decide whether a sufficiently common ground of agreement could be found so as to establish definitely an International Medical Press Association, to draw up a scheme of statutes for such an association, and to fix upon a place of meeting for a general congress which would confirm or amend this scheme. All these objects have been attained. A set of rules or statutes was adopted and it was decided that an International Congress of the Medical Press would be held a few days previous to the meeting of the International Medical Congress which is to assemble at Madrid during the month of April next year. This plan of action is now endorsed by the delegates of the medical-press associations of Austria, Bohemia, Belgium, Denmark, England, France, Germany, Holland, Italy, Norway, and Spain. In regard to the details of this conference the debates and the text of the resolutions adopted and a full and official report, based on shorthand notes taken at the time, will be published in the course of a few weeks. It will then be time enough to enter into the full consideration of, and to devote criticism to, the proceedings. For the moment it will suffice to give some account of the princely reception accorded to the 28 delegates who represented the above-mentioned nationalities.

The greater part of the delegates were received at the Hotel de Paris, where a special room was provided, so that they might have their meals together in private and discuss in an informal manner the business in hand. The formal opening ceremony was held on Monday, April 7th, in the Oceanographic Museum which was gracefully draped with flags of all nations and ornamented with flowers. The Prince of Monaco and suite were present Professor Cornil (Paris) presided and His Excellency M. Olivier Ritt, Governor-General of the Principality, delivered an eloquent address of welcome on behalf of His Most Serene Highness Prince Albert I. of Monaco. Dr. Godineau then spoke very gracefully in the name of the Monaco Medical Society and speeches from the foreign delegates followed. In the evening the members of the conference were received in state at the palace. On the Tuesday there were business meetings in the morning and the evening and in the interval a visit was paid to the yacht of the Prince of Monaco. This is the third yacht which Prince Albert has caused to be constructed for the purposes of scientific research. The first was called *l'Hirondelle* and with this ship he carried out his investigations at the Azores. These related mainly to fishing and to ocean currents. A great number of metallic and glass bottles containing written explanations were dropped into the sea and, being ultimately picked up on different and distant coasts, the directions of various currents were thus determined. With the second yacht, *Princess Alice*, experiments were made to test the depth of the ocean. The apparatus required for such purposes is so weighty that a third and much larger yacht had to be built which is also called the *Princess Alice*. It was this last-mentioned ship which the members of the medical press conference visited. Here they were able to examine the cable weighing three tons, by which apparatus can be let down to a depth of 6000 metres. Even at this great depth living organisms, mainly shell-fish, were discovered and captured. On board there are three laboratories, one above the other, for chemical analyses, the preservation of specimens, &c. Two expeditions were made to the Arctic regions where at some risk to his life the Prince was able to prove that the same sort of fish existed as in the tropics when the lower depths of the ocean were reached. The result of all these journeys and researches are collected together in the Oceanographic Museum which is built on the extreme and farthest edge of the rock of Monaco. This building is destined as a meeting-place for *savants* from all parts of the world and especial facilities will be afforded for the study of the secrets of the ocean. It was here that the Prince was anxious to welcome the representatives of the medical press, for, as he himself put it, if the origin of life may be found in oceanic protoplasm its preservation rests in the hands of the medical profession. It was, therefore, as a man of science addressing himself to brothers in science that the Prince was desirous of offering hospitality in his principality to the representatives of the medical press

---

[1] See THE LANCET, August 4th (p. 347), 11th (p. 454), and 18th (p. 520), 1900.

To terminate the second day of the Conference a gala representation was given to the delegates at the Monte Carlo Theatre. On the Wednesday, the third day, the conference met in the morning and in the afternoon and Prince Albert made a point of being present at the closing ceremony The delegates then proceeded with the Prince to assist at the inauguration of the new hospital which has just been built, and in the evening all the delegates dined with His Highness. But though the work of the conference was now terminated this did not conclude the entertainments offered On the following (Thursday) morning the delegates were taken by a special train to La Turbie where there remain the ruins of the great tower built by the Emperor Augustus Cæsar Here, high up among the offshoots of the Maritime Alps, the delegates were driven in carriages to the Nice Observatory After viewing the instruments of this magnificent institution they returned to Monaco by the lower Corniche road, thus enjoying some of the finest mountain and seashore scenery of Europe In the afternoon there was a classical concert and in the evening the delegates went to Nice where the mayor and municipality entertained them at a banquet at the new and palatial Imperial Hotel and at a gala performance at the opera house. It was not till after midnight that the delegates parted company on the platform of the Nice railway station. The members of the Monaco Medical Society wore special badges, by which they implied that they held themselves at the disposal of the delegates, and they all vied with each other in courtesy and in the rendering of every possible assistance. The greatest cordiality prevailed throughout, and for the successful issue of the conference the medical press is deeply indebted to His Highness Prince Albert I and to the Monaco Medical Society

Monaco, April 12th

THE ROYAL COLLEGES AND THE INVESTIGATION OF CANCER.

WE announced some two months ago that the Royal College of Physicians of London and the Royal College of Surgeons of England had come to a joint resolution to draw up a detailed scheme for systematic investigation into the causes, prevention, and treatment of cancer The delegates appointed by the two Royal Colleges have now submitted to their respective bodies the following scheme, and the subsequent step will be an influentially signed appeal to the public for pecuniary support.

DRAFT SCHEME

I —OBJECTS OF THE FUND

IN order to promote investigations into all matters connected with, or bearing on, the causes, prevention, and treatment of cancer and malignant disease steps shall be taken:—

1. To provide, extend, equip, and maintain laboratories to be devoted exclusively to cancer research

2. To encourage researches on the subject of cancer within the United Kingdom or in the British Dominions beyond the seas.

3. To assist in the development of cancer-research departments in various hospitals and institutions approved by the Executive Committee.

4 And generally to provide means for systematic investigation in various other directions into the causes prevention, and treatment of cancer.

Should the object of the fund be attained by the discovery of the cause and nature of cancer and of an effective method of treatment the Royal Colleges with the consent of the trustees shall be empowered to utilise the fund either (*a*) for equipping with the necessities for such treatment such hospitals as they may select, or (*b*) for forwarding research into other diseases.

The fund shall be administered by a president, vice-presidents, trustees, honorary treasurer, General Committee, and Executive Committee

II.—THE PRESIDENT, VICE PRESIDENTS TRUSTEES, AND TREASURER.

1. The first President shall be ——————
2. The first Vice-Presidents shall be ——————
3. There shall be five trustees of the fund

4 Of the first trustees three may be nominated by the donors of sums of £1000 and upwards and one each by the Royal Colleges of Physicians and of Surgeons.

5. In the event of vacancies occurring by death, resignation or other cause the general committee may nominate new trustees and shall be called upon to do so in case the number shall fall below three.

6. All moneys other than annual grants or subscriptions, or sums specially given for definite objects or under special conditions, shall be invested as capital in the names of the trustees.

7 The first honorary treasurer shall be

8. In the event of a vacancy in the post of honorary treasurer the general committee shall appoint some person to that office

9 The honorary treasurer may be one of the trustees.

10 The honorary treasurer shall be responsible for the receipt of all moneys on behalf of the fund

11 The honorary treasurer shall pay over to the account of the Executive Committee all annual grants and subscriptions, as well as any sums specially given for definite objects or under special conditions.

III —GENERAL COMMITTEE

1. The general committee shall consist of: (*a*) the president; (*b*) the vice-presidents, (*c*) the five trustees, (*d*) the honorary treasurer; (*e*) the Executive Committee, (*f*) one member to be nominated by the Local Government Board; (*g*) one member to be nominated by the Colonial Office, (*h*) one member to be nominated by the Royal Society, (*i*) one member each nominated by the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, the Faculty of Physicians and Surgeons of Glasgow the Royal College of Physicians of Ireland and the Royal College of Surgeons in Ireland; (*j*) one member each nominated by the Royal Veterinary College, London, the Royal Veterinary College, Edinburgh, and the Royal Veterinary College of Ireland (*k*) donors of sums of £1000 and upwards, whether given in one sum or more; with power to add to their number

2. The General Committee shall nominate two members of the Executive Committee who shall hold office for three years and shall be eligible for re-election

3 The General Committee shall meet from time to time to receive reports from the Executive Committee on the general progress of the scheme, an account of expenditure, and the audited financial statement

4 The office of the General Committee shall (with the consent of the Royal Colleges) be at the Examination Hall, Victoria Embankment.

IV —THE EXECUTIVE COMMITTEE

1 The Executive Committee shall consist of:—

(*a*) The President (for the time being) and two Fellows of the Royal College of Physicians of London	3
(*b*) The President (for the time being) and two members of the Council of the Royal College of Surgeons of England	3
(*c*) Two members of the Laboratories' Committee of the Royal College of Physicians and Surgeons	2
(*d*) Two members nominated by the General Committee	2
(*e*) One member nominated by the Royal Society	1
(*f*) One member nominated by the Royal Veterinary College London	1
	12

The members of the Executive Committee shall hold office for three years and shall be eligible for re-election

2. The Executive Committee shall have control of the income of the fund which shall be expended in furthering the objects stated in Section I, including the assignment of funds: (*a*) for the erection or extension of laboratories or for the equipment of any existing laboratory in which investigations are, or shall be, pursued; (*b*) for grants to individual workers in other laboratories or elsewhere; (*c*) for investigations other than those in laboratories; (*d*) for the collection of statistical dietetic, topographical, and other information; (*e*) for the salaries of any officials who may be appointed

3 The Executive Committee shall be charged with the general supervision and management of the arrangements to carry out the objects of the fund and shall be required to report their proceedings from time to time to the General Committee.

4 The Executive Committee may seek the advice of the members of the working and consultative staff on any questions relating to the objects of the fund and may appoint committees to conduct investigations or to collect statistics and information, and may provide funds for the expenses of these investigations and for the remuneration of the members of these committees.

5. The Executive Committee shall apoint the working and consultative staff under such conditions as they may think desirable.

6 The Executive Committee may make arrangements for investigating methods of treatment in cases of cancer and malignant disease.

7 The Executive Committee may make arrangements to establish a system of correspondence with foreign and colonial laboratories and workers.

8. The Executive Committee may appoint a general superintendent of the investigations who may be director of the central laboratory and such assistants as may be considered necessary

9 The Executive Committee shall draw up the regulations under which the work of the staff shall be conducted and shall determine the conditions under which laboratory accommodation at the Examination Hall or elsewhere may be provided

10. The Executive Committee may appoint a secretary or other official to conduct the correspondence, summon and attend the meetings, keep the accounts write the minutes, &c.

11 The Executive Committee may make contributions towards the development of the cancer research department of the Middlesex Hospital, or a similar department of any other hospital, if established

12. And generally the Executive Committee shall make such arrangements as shall seem to them best for the thorough investigation of this disease in all its aspects

V.—WORKING AND CONSULTATIVE STAFF

1 The working staff shall consist of:—(*a*) A general superintendent of the investigation who may be the director of the central laboratory; (*b*) assistants to the general superintendent and director; (*c*) any other persons who may be appointed to make special investigations

2. The consultative staff shall consist of persons skilled in scientific investigations, representatives of various home and colonial government departments, physicians and surgeons attached to hospitals, statistical experts and others, appointed by the Executive Committee.

3. The consultative staff may receive fees for attendance at meetings

and may be remunerated for any services performed in connexion with the objects of the fund, on such conditions as the Executive Committee may determine.

THE VOLUNTEER MEDICAL ASSOCIATION.

THE annual dinner of the above association was held at the Hotel Cecil on April 9th, Surgeon-General W. TAYLOR, C.B., Director-General of the Army Medical Service, being in the chair. About 75 members and guests were present and amongst the latter were Surgeon-General Keogh, C.B., Deputy Director-General, Lieutenant-Colonel W. Babtie, V.C., R.A.M.C., Major W. G. Macpherson, R.A.M.C., and Colonel W. L. Gubbins, R.A.M.C., Principal Medical Officer of the Home District. Among the members supporting the chairman of the association, Brigade-Surgeon-Lieutenant-Colonel A. Clark, were the following:—Brigade-Surgeon-Lieutenant-Colonels Russell, Raglan, H. G. Thompson, G. Danford Thomas, H. W. Kiallmark, and C. Boyce; Surgeon-Lieutenant-Colonels M. Baines, F. W. Humphreys, A. Cooper, Adams, R. T. A. O'Callaghan, A. T. Norton, C.B., W. Gandy, and W. D. Waterhouse; Surgeon-Majors C. Godson, Dundas Grant, W. Culver James, F. E. Fenton, A. H. Robinson, W. J. Harnett, and J. J. de Z. Marshall; and Surgeon-Captains J. Cantlie, Macgregor, T. H. Openshaw, C. A. Goullet, and Sharpe.

After the usual loyal toasts had been proposed and heartily responded to Mr. HOWARD MARSH proposed "The Imperial Forces."

The CHAIRMAN then proposed the toast of the evening, "Success to the Association," and in the course of his remarks he alluded to the recent letters from the War Office sanctioning certain changes in respect to the Volunteer Medical Service, stretcher-bearer companies, &c. All that had been asked for had not been granted, but in future the bearer companies were to be separate units and to become an integral part of their respective brigades, the channel of communication being through the senior medical officer of the brigade. These units would draw their own capitation grants and other allowances, and a sergeant-instructor of the Royal Army Medical Corps would be attached to each company. An ambulance wagon would also be issued for drill purposes to each company. Should a bearer company find it convenient to make its headquarters the same as that of any particular battalion in the brigade and to become attached to the same, and should satisfactory arrangements be made, it might do so, but the members thereof would be supernumerary in every respect to the authorised establishment of the battalion. These arrangements would not interfere with the regimental medical officers who would continue to train regimental stretcher-bearers in the proportion of two men per company. With the exception of the Royal Army Medical Corps Volunteers, the compound titles would still continue to exist. With regard to increasing the number of brigade stretcher-bearers to 110 rank and file so as to provide for a field hospital no order had yet appeared, but, added Surgeon-General Taylor, anything that he could do to support this proposition he would do gladly as he appreciated the necessity for, and advisability of, the increase suggested. He concluded by expressing the opinion that the Volunteer Medical Association was doing good service and had done much in effecting the changes already mentioned; and in proposing success to the association he had much pleasure in coupling with the toast the name of Brigade-Surgeon-Lieutenant-Colonel A. Clark, the chairman of the council, and in expressing the hope that every volunteer medical officer would become a member of the association.

Brigade-Surgeon-Lieutenant-Colonel CLARK replied, and in thanking the Director-General for his kind promises of help so far as it lay in his power in perfecting the volunteer medical organisation he referred to the work of the council during the past year, which in a great measure had resulted in the changes of which they had heard that evening. They would be glad to have as members all the volunteer medical officers, and he looked forward to an increase in numbers in the course of the present year. Classes of instruction were arranged for those officers who wished to present themselves for examination and there was a very handsome challenge shield which was competed for annually by regimental stretcher-bearers. The council was always ready to receive and to consider all communications from members and their experiences, and when occasion required to take active steps towards obtaining improvements or reforms, and this could often be done more effectually by an organised association than by individual effort only. He thanked the Director-General for his presence that evening, and all those present for their hearty response to the toast.

Brigade-Surgeon-Lieutenant-Colonel DANFORD THOMAS proposed the toast of "The Visitors," which was responded to by Colonel GUBBINS, R.A.M.C.

The toast of "The Chairman" was then given by Surgeon-Lieutenant-Colonel A. COOPER, and was received with musical honours.

The DIRECTOR-GENERAL replied and then proposed the health of Surgeon-Major Marshall, the honorary secretary, in doing which he thanked him for the able manner in which he had arranged all the details for their entertainment that evening. This was warmly responded to.

During the evening selections of vocal music were given by the members and their friends.

THE ROYAL ORTHOPÆDIC HOSPITAL.

THE annual meeting of the Court of Governors of this hospital was held on April 10th at 15, Hanover-square, W., when Mr. H. Marks, the chairman of the Committee of Management, presided.

Dr. DAVID WALSH called attention to certain omissions from the report, as did also Mr. REEVES. Considerable discussion followed, but eventually the report was adopted. The report stated that the subscriptions amounted to £438, as compared with £452 in the previous year, and the donations to £475, against £547 in 1891. The income, exclusive of legacies, had reached £1900. King Edward's Hospital Fund had given a grant of £200. The total expenditure for the year had been £2881, being £65 less than in the previous year. The in-patients admitted were 255. In the out-patient department there were 1060 new patients and 4390 attendances. The total number of patients benefited by the hospital since its foundation had been 84,452. Mr. Marks was then elected chairman of the Committee of Management and the following gentlemen were appointed members of that committee: Mr. E. Flower, M.P., the Hon. Claude G. D. Hay, M.P., Mr. James Head, Major Ricarde-Seaver, Mr. H. A. Reeves, Mr. W. Gordon Campbell, Mr. Frank Mathews, and others. Mr. R. B. Martin, M.P., was re-elected honorary treasurer. The honorary surgeons and the auditors were also re-elected. Mr. Marcus Cuerton was elected a vice-president in consequence of the large amount of financial help which he had given to the hospital. Various officers were then reappointed. This concluded the business of the court and a special court was constituted to discuss the question of the hospital site and other matters. On the question of the hospital site Mr. MARKS moved:—

> That the agreement made by the Committee of Management for the disposal of the existing site, having received the approval of the trustees and the Charity Commissioners, be ratified, and the governors hereby authorise the committee to take all necessary steps for the acquisition of the site and the erection thereon of a new hospital.

He said that the work of the hospital had been frequently hampered and seriously interrupted on several occasions owing to the unsatisfactory condition of the premises. The total cost of repairs had been £2160, an average of £432 per annum. In 1899 the committee of the hospital wished to sell the site for £28,000. This led to the appointment of a new committee who subsequently received an offer for the purchase of the site on a basis of 29 years' purchase at £1300 per annum, or £37,700. Subsequently a proposal was made that the site should be leased for 99 years at an annual rental of £1400 and that the lessees should have the option during three years to purchase at £40,000. The trustees considered this offer favourable and they recommended its acceptance. The Charity Commissioners considered the offer favourable and so did the committee. The present site was unsuitable for the reconstruction of a new hospital upon modern plans and approved lines.

Dr. WALSH said he thought that the scheme put forward was unbusinesslike. He had been told by an expert valuer that the present site of the hospital was worth £63,000. The matter ought to be referred to a court of abitration or the value tested by putting the site up to public auction, and o alleged that the present meeting was illegal, inasmuch s the rules of the charter of incorporation had not been omplied with and any person buying the hospital would do o on an insecure tenure.

Mr E. FLOWER, M.P., supported the motion.

Mr R B MARTIN, M.P., regretted that it should be ecessary to remove the hospital, but he had come to the onclusion that there was no other alternative.

Mr REEVES took the point of view that the present site ught to be retained.

After a prolonged discussion Mr FLOWER moved that the uestion be now put. This was carried and the original motion was adopted

ROYAL COLLEGE OF SURGEONS OF ENGLAND

A QUARTERLY meeting of the Council was held on April 10th, Mr HENRY G HOWSE, the President, being in he chair

Sir William H Bennett, K.C.V.O., Mr. Frederic S. Eve, nd Mr W Watson Cheyne, C.B., made declarations in the erms of the oath prescribed by the Charter of 1800 and were admitted members of the Court of Examiners.

It was resolved to connect the College with the telephone ystem

The subject for the Jacksonian Prize for the year 1903 was hosen—namely, "The Various Forms of Conjunctivitis heir Pathology and Treatment."

On the recommendation of the Nomination Committee it was resolved :—

> That it is inexpedient that any member of the Court or of any Board of Examiners of the College should conduct or assist in conducting any preparatory or special course of instruction or tutorial class, either with or without emolument, in the subject in which he is an examiner other than his recognised and regular course

Sir William Bennett and Mr C H. Golding Bird were elected members of the Court of Examiners Section of the Board of Examiners in Dental Surgery

Mr William Henry Power, principal medical officer of the Local Government Board, and Dr George Bagot Ferguson President of the British Medical Association, were elected to the Fellowship as Members of over 20 years' standing

A draft scheme for organising cancer research was submitted and the Council gave its general approval to the scheme.

Mr F Richardson Cross was nominated a delegate of the College to the annual congress of the Royal Institute of Public Health to be held in Exeter from August 21st to 26th.

THE METROPOLITAN WATER-SUPPLY

VII [1]

THE NEW RIVER COMPANY

THE New River is the oldest of all companies which supply water to London and of late years it is one of those which has given little cause for complaint on the part of its customers Readers of some of the previous articles of the present series cannot have failed to notice that the quality of the water supplied by the New River Company has been proved to be superior to that distributed by many of the other undertakings It is, however quite true that in regard to the absence of constant service complaints have been made in the City of London within the last few years, but in this case the citizens had no just right to expect sympathy, for the remedy has long been in their own hands and their own apathy alone deserves blame. The citizens have also intermittently and rather plaintively complained of the price which they have had to pay for the water,[2] yet the New River Company has not exacted and doubtless has been well advised in not exacting, the full rents which were due under the statutory regulations which fix the maximum charges. The full title of the company is "The Governour and Company of the New River brought from Chadwell and Amwell to London" The Acts for enabling the enterprise to be carried out were passed in the early years of the reign of James I (3 James I, c. 18, and 4 James I., c. 12) and the company was afterwards incorporated (June 21st, 17 James I) It is not necessary here to give an account of the early history of the adventure and those who may be interested in the original charter will find it amongst the Patent Rolls at the Record Office, No 2214 (67) It is not without importance to note that of the original sources of supply the Amwell spring has long ceased to discharge its water into the New River and that the flow of the Chadwell springs has been steadily diminishing during the last few years—a fact very clearly brought out by Lord Robert Cecil at the Llandaff Commission. More than one attempt was made to obtain the sanction of Parliament to the charter of James I and Bills to that effect were introduced into the House of Commons in 1621, in 1623, and in 1642. It seems, however, that the Members objected to confirm a monopoly by Act of Parliament.

The first Act obtained by the company after the reign of James I was passed in 1738 (12 Geo. II c. 32) and by this Statute the company was allowed to take water from the river Lee upon the payment of an annual sum which was to be spent in improving the navigation of the river In addition to this only two Acts having reference to the company where passed before the middle of the last century (12 Geo II cap 32 and 3 Geo IV c. 109). In the year 1850 the sources of supply of the company were the river Lee, Chadwell springs, and wells at Amwell, Amwell hill, Cheshunt, and Hampstead road There were two reservoirs at Cheshunt comprising an area of over 18 acres, two at Stoke Newington having an area of 42½ acres, and one reservoir at New River head having an area of five acres. None of the water was filtered and the only method of purification adopted was that due to subsidence. At Cheshunt, where the water was derived from the higher ground to the north of the reservoirs, it was generally retained for a month to undergo purification The company maintained that the water was also much improved in passing down the New River in the course of its transit. The current flowed gently and there was therefore "much time for the deposit of any alluvial matter" which it might contain, and this was markedly the case at five enlarged portions of the river

Between the years 1850 and 1855 considerable alterations were effected in the works of the company, but it is evident from the remarks on the undertaking contained in the reports made to the General Board of Health[3] that there was considerable delay in making necessary improvements. The Metropolis Water Act had then been passed and the company had obtained three additional private Acts (15 and 16 Vict., c. 160, 17 Vict. c. 39, and 17 Vict., c. 72) Of these, one enabled the company to divert the Hertford sewerage from the point at which it entered the Lee above the intake which led to the New River but nothing has been done towards carrying out the work. On this matter the report referred to having emphasised the fact that at that time the Lee was the main source of the company's supply, continued to point out that "under these circumstances it does seem important that the drainage of Hertford which discharges immediately above this source of supply should be diverted from it," and a hope was expressed that the powers obtained by the company to effect this object would soon be put into operation. It is evident that at this period the sources of the water were open to objection. In regard to other important matters, however, improvements had been made. Five filter beds, having together an area of six and a half acres, had been constructed at Stoke Newington, three filter beds covering an area of two and a half acres had been made at the New River head Claremont-square reservoir had been covered over (as required by the Metropolis Water Act 1852) and two new covered service reservoirs had been built at Maiden lane. It seems rather curious that at this period the "length of pipage possessed by the company" was not accurately known The quantity of water pumped for distribution daily was 25 000 000 gallons and the number of tenements supplied was 95 083. The supply was given "daily,

[1] Articles I, II III, IV V and VI appeared in THE LANCET of March 1st (p 614), 8th (p 692), 15th (p. 767), 22nd (p. 842) and 29th (p. 915) and April 5th (p 985) 1902, respectively

[2] At the Llandaff Commission the City Remembrancer suggested that the price paid was not less than that which would have been paid for beer The charges due are made on the rateable value of a property not on the amount of water consumed on the premises

[3] General Board of Health Reports to the Right Hon William Cowper M P President of the General Board of Health on the Metropolis Water-Supply under the provisions of the Metropolis Water Act London 1856.

Sundays excepted," to all parts of the district "and where necessary in the poorer localities" on Sundays also. It is noted in the report already quoted that "the New River head is not a very desirable locality for filter beds." It seems somewhat strange that the Clerkenwell station should have remained in use for that purpose even to the present day; it shows a truly conservative spirit on the part of the directors of the company, and from a sentimental point of view it would be a matter for much regret should the New River head be destroyed.[4]

Of late years very many improvements have been made in the works of the New River Company and the way in which the New River itself has been kept has of late, we believe, been in accord with the best traditions of the enterprise. A full description of the river itself and of the method by which it was protected and the manner in which it was worked was given in THE LANCET Special Commission on the Metropolitan Water Supply.[5] It is unnecessary to repeat what was there stated. At the time at which the survey was made much had recently been done to ensure the purity of the river and the company had not, as was the case with many of the other undertakings, a large amount of accumulated arrears of neglected work to make good. Table I. gives in parallel columns statistical details compiled from information given by the New River Company for the month of June, 1897, and the corresponding figures derived from the Water Examiner's report for the month of June, 1901.

TABLE I.—*Giving Statistical Details for the Month of June, 1897, and the Month of June, 1901, from Information given by the New River Company and the Report issued by the Water Examiner*

—		June, 1897.	June, 1901.
Supply	Average daily supply in gallons (filtered) ...	34,646,498	39,650,229
	Number of houses supplied	162,169	173,060
	Number of houses on constant supply	129,017	164,529
	Estimated population supplied	1,176,000	1,254,685
Reservoirs, subsiding and storage	Number	20	20
	Area in acres	99½	99½
	Available capacity in gallons	168,100,000	168,100,000
Storage filtered water reservoirs	Number	11	12
	Capacity in gallons ...	37,540,000	38,240,000
Water-pipes... ...	Total number of miles of water-pipes	841	880
	Number of miles of water-pipes in the metropolis	781	806
	Number of hydrants erected within the metropolis: public fire ...	6,517	7,723
	street-watering	618	715
	private fire ...	4,296	5,154
Filters	Number of beds	20	20
	Area in acres	16¼	16¾
Sources and amount of water filtered and pumped, daily average in gallons	Springs and wells	13,359,635	19,057,410
	River Lee	21,286,863	20,592,816
Sources and amount of water delivered unfiltered, daily average in gallons ...	Ponds	3,904	2,149
	Springs and wells	2,197,261	2,298,696
	River Lee	1,148,337	1,842,395

The table shows that no great changes were made in the arrangements of the company between June, 1897, and June, 1901. The most noteworthy thing in the table is, perhaps, the fact that an increased amount of water was derived from "springs and wells" during the later period (June, 1901). It is to be regretted that full particulars are not accessible as to the amount of water derived from each of the wells possessed by the company. In the so-called "details" supplied to the Water Examiner the whole amount of water derived from springs and wells is given, but there is absolutely no "detail" as to the amount derived from any particular well. It is known that the pumping at one well affects the water level at another well belonging to the company, but the most obstinate reticence has been adopted by the directors in withholding information as to the water level in the wells. A great deal of evidence has been given by independent witnesses as to the way in which that part of the county of Hertfordshire which is adjacent to the pumping stations of the New River Company has of late years suffered from the depletion of water, and it is a matter of great importance that the exact state of the case should be known. If one of the most important recommendations given by the Balfour Commission had been acted upon the facts would now be known accurately.

The sources from which the New River obtains the water for drinking purposes are the River Lee and a number of wells, but to provide for future contingencies the company has joined in the Staines reservoir scheme and therefore in the ordinary course of events the customers of the company will some day be supplied in part at least by water derived from the Thames. During last year the water supplied by the company was generally of excellent quality, but it contained more organic carbon and more organic nitrogen than that supplied by the Kent Company. The results of the examinations made by the analyst appointed by the Local Government Board are given in Table II. It will be noticed that the quality of the Kent water varied very little, but that of samples taken of the New River water was not always equally good.

TABLE II.—*Showing the Results of Analysis expressed in Parts per 100,000 of Organic Carbon and of Organic Nitrogen in the Water supplied by the West Middlesex Waterworks Company, the New River Company, and the Kent Company in each Month of the Year 1901 and in the Month of January, 1902. (Compiled from the Reports of the Results of Analysis made by Dr. T. E. Thorpe, F.R.S., on behalf of the Local Government Board.)*

In Dr. T. E. Thorpe's report on the sample of water examined in March, 1901, he says: "The New River Company's water during March was inferior to that delivered in February, mainly on account of the higher amounts of organic matter found in samples taken in the middle of the month"; he adds, "this company's water was, however, always superior to that of the Thames companies." The sample of which the one full analysis was made was taken on March 16th from the cab rank, Tottenham-court-road. Dr. Thorpe's report on the water analysed in April states that "the New River water was much ...... superior to any of the Thames-derived supplies." The one sample of which a full analysis was made was taken from the cab rank at Canonbury station. In regard to the supplies given in

---

[4] Myddelton here built a house for the Governor of the company; it must have been a most pleasant place.

[5] THE LANCET, Oct. 23rd to Dec. 18th, 1897, inclusively.

September Dr Thorpe says that "the New River Company's water on a few occasions was found to contain somewhat more organic matter than usual." It will be seen that the results of the one full analysis made during that month which are given in the above table show this increase. The sample was taken from the cab rank near St. Clement's Danes Church, Strand, on Sept. 10th Dr Thorpe further says that "from information supplied by the secretary of the company it appears that these abnormal results were due to an admixture of filtered Thames water, this being necessary in connexion with the arrangements whereby the East London Company has been assisted during the past month" From this it is evident that the New River Company cannot always "assist" the East London Company without prejudicing the interests of its customers by supplying them with water of a quality inferior to that to which they have been accustomed. The present working of the intercommunication scheme is certainly unfair to them and it ought not to be allowed to continue for an indefinite time.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Cardiff Port District.—In his report for the last quarter of 1901 Dr Edward Walford gives the results of the examination in a bacteriological sense of samples of drinking water taken from vessels frequenting this port. The number of micro-organisms at 37° C. ranged from 36,000 per cubic centimetre to 76 per cubic centimetre Although no information is given as to the nature of any of the organisms found the numbers detected in several instances suggest the need of a reform in the methods of water storage on board the vessels from which the samples were taken. Cardiff is an important channel through which frozen meat finds its way from South America into this country, and it is assuring to learn that this meat is duly inspected on arrival and that a notice of the destination of the cargo is sent to the sanitary authority of the district to which the meat is consigned.

Aston Manor Urban District.—The vital statistics of this district within recent years are not altogether encouraging to the sanitary administration of the council When the figures for 1882–91 are compared with those for 1892 1901 the only diminution detectable is in the birth rate which has fallen from 34·1 to 33·2 per 1000. The general death rate has increased from 16·1 to 16·4 per 1000 and the zymotic death-rate from 2·7 to 3·5 per 1000, while the infantile mortality has risen from 145 to no less than 177 per 1000 births. Infantile diarrhoea seems, as usual, to have accounted for much of this latter mortality but this does not adequately explain why the total infantile mortality has gone on increasing In order to arrive at an accurate conclusion as to this the causes of the deaths of infants should be further differentiated and contrasted year by year. As Mr Francis H. May remarks this increasing infantile mortality will result in altering the age distribution of the population.

Crewe Urban District.—Dr Alfred Greenwood, the medical officer of health of this district, made an effort during 1901 to bring about the notification of sickness through the agency of the 27 friendly societies in Crewe. The corporation offered to pay to the secretaries of these societies a fee of 2*d*. per case. But this reward induced only 17 out of the 27 societies to respond. Dr Greenwood explains that he hoped in this manner to obtain information with regard to cases of phthisis and diarrhoea which would otherwise not be brought under his notice It is not stated if the cost of postage is defrayed by the corporation and in view of the small amount here in question this item may be worth *consideration*

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN 76 of the largest English towns 9494 births and 4971 deaths were registered during the week ending April 12th. The annual rate of mortality in these towns, which had been 18·2 and 17·6 per 1000 in the two preceding weeks, further declined last week to 17·4 per 1000 In London the death rate was 17·3 per 1000, while it averaged 17·5 in the 75 other large towns The lowest death-rates in these towns were 5·5 in Hornsey, 7·8 in Reading, 9·1 in Newport (Mon.), 10·1 in Leyton, 10·8 in Bury, 11·0 in Bournemouth, 11·1 in Wallasey, and 11·2 in Warrington; the highest rates were 22·1 in West Bromwich, 22·2 in South Shields, 22·3 in Barrow in Furness, 25·2 in Huddersfield, 25·9 in Hanley and in Merthyr Tydfil, 26·0 in Burnley, and 28·5 in Middlesbrough. The 4971 deaths in these towns included 596 which were referred to the principal zymotic diseases, against 602 and 572 in the two preceding weeks, of these 596 deaths 161 resulted from measles, 145 from whooping cough, 94 from small-pox, 85 from diphtheria, 45 from scarlet fever, 44 from diarrhoea, and 22 from "fever" (principally enteric) No death from any of these diseases occurred in Hornsey, Bournemouth, Reading, Ipswich, Handsworth, Smethwick, Wallasey, Warrington, Bury, York, or West Hartlepool, the highest zymotic death rates were recorded in Tottenham, West Ham, Hanley, Burnley, Blackburn, Barrow in Furness, Middlesbrough, and Stockton. The greatest mortality from measles occurred in Willesden, Oldham, Rochdale, Burnley, Blackburn, and Barrow in Furness, from scarlet fever in Burton on-Trent, West Bromwich, and Stockport, from diphtheria in Portsmouth, Hanley, Burnley, Middlesbrough, and Rhondda, from whooping-cough in Devonport, Wolverhampton, Aston Manor, Barrow in-Furness, Stockton, and South Shields, and from diarrhoea in Walsall and King's Norton The mortality from "fever" showed no marked excess in any of the large towns. The fatal cases of small pox registered last week included 73 in London, 15 in West Ham, three in Tottenham, two in Swansea, and one in Walthamstow The number of small-pox cases under treatment in the Metropolitan Asylums hospitals, which had been 1567, 1528, and 1522 at the end of the three preceding weeks, had further declined to 1437 on Saturday, April 12th, 274 new cases were admitted during the week, against 449, 389, and 376 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of last week was 2146, against numbers decreasing from 3137 to 2126 on the 15 preceding Saturdays, 264 new cases were admitted during the week, against 258, 250, and 228 in the three preceding weeks The deaths referred to diseases of the respiratory organs in London, which had been 388, 360, and 317 in the three preceding weeks, further declined last week to 299 and were 67 below the corrected average number The causes of 59, or 1·2 per cent, of the deaths in the 76 large towns last week were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in West Ham, Nottingham, Salford, Bradford, Leeds, Newcastle, and 41 other smaller towns, the largest proportions of uncertified deaths were registered in Liverpool, Wigan, Warrington, Blackburn, Sunderland, and South Shields

HEALTH OF SCOTCH TOWNS

The annual rate of mortality in the eight Scotch towns, which had been 20·3 and 21·3 per 1000 in the two preceding weeks, further rose to 22·1 per 1000 during the week ending April 12th, and was 3·7 per 1000 in excess of the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 13·9 in Leith and 20·1 in Edinburgh to 25·1 in Aberdeen and 26·5 in Greenock The 715 deaths in these towns included 21 which resulted from whooping-cough, 10 from measles, eight from scarlet fever, eight from diarrhoea, five from "fever," two from small pox, and two from diphtheria. In all 56 deaths resulted from these principal zymotic diseases last week, against 59 in each of the two preceding weeks. These 56 deaths were equal to an annual rate of 1·7 per 1000, which was 0·4 below the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 13 and 14 in the two preceding weeks, further increased last week to 21, of which eight occurred in Aberdeen, seven in Glasgow, two in Edinburgh, and two in Dundee The deaths from measles, which had been 14 and 11 in the two preceding weeks, further declined to 10 last week, and included four in Glasgow, three in Edinburgh and two in Dundee The fatal cases of scarlet fever, which had been three and eight in the two preceding weeks, were again eight last week and included four in Glasgow and three in Greenock. The deaths from diarrhœa, which had been 25, 22, and 15 in the three preceding weeks, further declined last week to eight, of which three were registered in Leith, two in Glasgow, and two in Edinburgh. The fatal cases of "fever," which had been four, one, and four in the three preceding weeks, further rose to five last week and included three in Glasgow. The two deaths from small-pox corresponded with the number in the preceding week and both occurred in Glasgow, where the two fatal cases of diphtheria also were recorded. The deaths referred to diseases of the respiratory organs in these towns, which had been 217, 173, and 160 in the three preceding weeks, rose again last week to 188, and were 33 in excess of the number in the corresponding period of last year. The causes of 34, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 22·4, 27·5, and 26·8 per 1000 in the three preceding weeks, further declined to 26·7 per 1000 during the week ending April 12th. During the past four weeks the death-rate has averaged 25·9 per 1000, the rate during the same period being 18·6 in both London and in Edinburgh. The 194 deaths of persons belonging to Dublin registered during the week under notice showed a slight decline from the number in the preceding week, and included 11 which were referred to the principal zymotic diseases, against seven and six in the two preceding weeks; of these, four resulted from diarrhœa, three from measles, two from whooping-cough, and two from "fever." These 11 deaths were equal to an annual death-rate of 1·5 per 1000, the zymotic death-rates during the same period being 2·6 in London and 1·4 in Edinburgh. The deaths from measles, which had been one in each of the three preceding weeks, increased last week to three. The mortality from whooping-cough, from "fever," and from diarrhœa was also in excess of that recorded in the preceding week. The 194 deaths in Dublin last week included 34 of children under one year of age and 47 of persons aged upwards of 60 years; the deaths of infants slightly exceeded the number in the preceding week, while those of elderly persons showed a slight decline. Six inquest cases and six deaths from violence were registered during the week, and 83, or more than two-fifths, of the deaths occurred in public institutions. The causes of 12, or more than 6 per cent., of the deaths registered in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: G. D. Twigg to the *Duke of Wellington* and Anthony Kidd to the *Benbow*. Surgeon T. B. Shaw to the *Duke of Wellington*.

IMPERIAL YEOMANRY (IN SOUTH AFRICA).

35th Battalion: John J. Scanlan to be Medical Officer, with the temporary rank of Captain.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel Henry J. W. Barrow to be Colonel, vice E. Townsend, promoted. Dated Sept. 25th, 1901.

Lieutenant-Colonel Robert Oriel Cusack retires on retired pay on account of ill-health. Dated April 16th, 1902.

The undermentioned officers retire on retired pay (dated April 16th, 1902):—Lieutenant-Colonel George Herbert Le Mottée and Lieutenant-Colonel R. W. E. H. Nicholson.

Captain J. Grech joins at Aldershot and is posted to the Connaught Hospital for duty. Major C. T. Blackwell, Aldershot, proceeds to South Africa. Major G. T. Alexander rejoins at Aldershot from a tour of trooping duty, and is posted to the Connaught Hospital.

ROYAL ARMY MEDICAL CORPS (MILITIA).

Supernumerary Lieutenant J. Clarke to be Captain and to remain seconded.

IMPERIAL YEOMANRY.

Nottinghamshire (Sherwood Rangers): George Thomson to be Surgeon-Lieutenant. Northamptonshire: Edward Milward Knott to be Surgeon-Lieutenant.

The undermentioned officers resign their commissions and receive new commissions subject to the provisions of the Militia and Yeomanry Act, 1901, each retaining his present rank and seniority, viz.:—

Royal North Devon (Hussars): Major and Honorary Lieutenant-Colonel W. N. Hoare and Surgeon-Captain J. R. Harper. Fifeshire and Forfarshire: Surgeon-Captain T. F. Dewar. Herts: Surgeon-Captain L. Drage. Lanarkshire: Surgeon-Major R. E. Wood. Norfolk (King's Own): Surgeon-Captain J. F. Gordon Dill. Warwickshire: Surgeon-Captain R. Bullock.

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Banff: Norman Davidson to be Surgeon-Lieutenant. 1st Edinburgh (City): Surgeon-Lieutenant R. B. Purves to be Surgeon-Captain.

Royal Engineers (Volunteers): East London (Tower Hamlets): John William Thomson Walker to be Surgeon-Lieutenant.

Rifle: 1st Volunteer Battalion the Manchester Regiment: Surgeon-Lieutenant J. Orr to be Surgeon-Captain. 2nd Cadet Battalion the King's (Liverpool Regiment): Frederic Henry Allfrey to be Surgeon-Lieutenant 3rd Volunteer Battalion the Lincolnshire Regiment: Henry Stanley Walker to be Surgeon-Lieutenant.

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

The Woolwich Companies: Supernumerary Lieutenant M. Taylor to be Captain and to remain Supernumerary. The Maidstone Companies: John Monkhouse Rogers-Tillstone to be Lieutenant

VOLUNTEER INFANTRY BRIGADE BEARER COMPANY.

4th London: Surgeon-Captain A. O. Tunstall, from the 1st Tower Hamlets Volunteer Rifle Corps, to be Surgeon-Captain, and to command the Company under paragraph 55A Volunteer Regulations.

SOUTH AFRICAN WAR NOTES.

Civil Surgeon Miles, dangerously wounded, was reported slightly improved on April 11th.

The following have been discharged from hospital to duty:—Lieutenant-Colonel J. C. Culling, R.A.M.C., Major S. Butterworth, R.A.M.C., and Civil-Surgeons Corby and Balfour.

THE DUTY OF THE MEDICAL DEPARTMENT ON THE FIELD OF BATTLE.

In a recent discourse pronounced by Dr. Choux, principal medical officer of the Paris garrison, with reference to the special military medical manœuvres which were held under the auspices of the commandant of the city, allusion was made, amongst other important matters, to the duty of the medical department on the field of battle. The subject is one that has excited great attention of late years, and evidently there is now a tendency to question the expediency of exposing non-combatants within the zone of fire. The spectacle of a medical officer, adequately seconded, amputating a wounded man's leg under a hail of missiles is certainly very fine and flattering, but, unfortunately, says Dr Choux, it *is based on a false conception* of the condition of things during a battle and by no means represents the reality. What the wounded man wants is to be placed in a safe place. As Lehrnbecker has it: "He has now only one desire, one object—to be withdrawn out of reach of additional wounds which will make an end of him." General Verdy du Vernois in his "Studies" doubts whether medical officers and their subordinates render any real service under fire. Port, who went through the war of 1870–71, shares this view, and so likewise do the German surgeons Peltzer and Scholtz. Pirogoff, the veteran, is of opinion that a medical officer in going under fire loses valuable time which might be better employed elsewhere. Summing up the argument Dr. Choux comes to the conclusion that medical officers should only venture into the fighting line during pauses. An engagement in these days is not continuous. There are intervals of calm, of tacit truce, and the surgeon should, without losing an instant, take advantage of these to explore the field and to remove the wounded. Stopping to dress them where they lie is time wasted and the wounded themselves would much prefer to be taken as quickly as possible to a place of safety. Absolutely indispensable dressings alone should be applied, for the action may again become active at any moment. In fine a medical officer's duty on the field of battle consists, says Dr. Choux, first, in removing his patient out of danger; secondly, in ministering to his sufferings, and especially to his thirst; and thirdly, in attending to his wounds. 99 out of 100 wounded men would welcome the appearance of trained bearers rather than that of the most skilful surgeon.

THE MEDICAL STAFF CORPS.

Mr. W. Carlile, M.P., who recently introduced a deputation of medical officers to Lord Raglan, has received from Sir E. W. D. Ward, Permanent Secretary of the War Office, a letter communicating the decision of the Secretary of State upon the points raised. The following are some of the more material portions of the official reply:—

> While the Volunteer Medical Staff Corps, officers and men, have been affiliated to the Royal Army Medical Corps, under the title of the Royal Army Medical Corps (Volunteers), by Army Order 28 of 1902, and the compound title of the officers abolished, Mr. Brodrick does not consider it advisable to interfere with the position of medical officers belonging to regiments or corps, their *status* being quite different from that of officers of the Royal Army Medical Corps (Volunteers).
>
> Mr. Brodrick further does not consider there is any necessity for the appointment of a volunteer medical officer to the office of the Director-General, or as a member of the advisory board for army medical services, as the interests of the volunteer medical service are already considered and duly safeguarded. It is also deemed unnecessary to introduce additional examinations for promotion. Mr. Brodrick, however, is of opinion that the period of service required for promotion to the rank of Surgeon-Major, or Major, in the Royal Army Medical Corps (Volunteers) should be reduced from 15 years to 12, and intimates that steps will be taken accordingly. The formation of the bearer companies of the volunteer infantry brigades as independent units has been authorised, and Mr. Brodrick trusts that this step may be to the advantage of the whole volunteer medical service, and that it will add to the efficiency of the brigades themselves. Careful consideration is being given to the questions of the provision of equipment and the allotment of volunteer medical officers for duty on mobilisation. The rates of pay and allowances for volunteer medical officers of all branches of the service have been arrived at after mature consideration and it is not apparent that there is any reason for departing from the scales approved.

The communication concludes with the announcement that the Secretary of State is prepared to approve of the granting of a step of honorary rank (on retirement only) under the same conditions as those operating for other branches of volunteers up to and including the rank of Honorary Surgeon-Colonel, or Colonel, in the Royal Army Medical Corps (Volunteers).

FOREIGN AMBULANCES FOR SOUTH AFRICA.

Aid to the sick and wounded in war on the part of neutral powers has, theoretically speaking, much to commend it to support and encouragement if only on the score of humanity, but nevertheless it opens up some difficult questions. It appears that Vicomte Villebois-Mareuil applied to the War Office for permission to supply an ambulance with its staff and accessories to the Boers in South Africa. While the receipt of the Vicomte's application was acknowledged in courteous terms befitting the occasion his request was not acceded to owing to the fact that similar requests received from other foreign Red Cross societies had been refused. It had been found that these foreign ambulances had not been always used exclusively for their intended purpose. It may be easily understood that ambulances and international systems of relief of this kind may, with the best intentions in the world on the part of their promoters, be open to this objection, especially where the sympathies are strongly on one side or the other. Moreover, the tendency of such organised systems, it might be urged, is, by taking care of their sick and wounded, to relieve the belligerents of much of the cost and responsibility of war. In proportion as a Government has not to provide for its sick and wounded the more money will it have to spend in the purchase of shot and shell and the better will a general be enabled successfully to prosecute a campaign. It is extremely difficult, too, for an international aid society to balance its services equally and fairly between two belligerent forces. With national aid societies the case is altogether different, for here the nation and the Government are supposed to be animated by a common purpose and to the working together to a common end.

MEDICAL AID TO THE WOUNDED DURING THE SEA BATTLES OF THE FUTURE.

In a recent article in the *Archives de Médecine Navale* Dr. Léo protests vigorously against what he maintains is the prevailing and paralysing notion that in the naval battles of the future the wounded will have to be left untended during the progress of active hostilities. With the best will in the world, it was argued, the inevitable condition of things at such times would render effective medical intervention an impossibility; and, moreover, owing to the multiplicity of indispensable fighting material with which modern warships are encumbered, there is no space available for properly constructed hospitals. These arguments were repeated over and over again *usque ad nauseam*, but they were none the less misleading fallacies. For many years Dr. Léo has combated these deplorable errors, not only exposing their lack of foundation, but also indicating the remedy. There is nothing chimerical, he says, or incapable of realisation in his *desideratum*. As he lately showed the *Suffren*, a new French ironclad, lends itself extremely well to the kind of medical installation which he recommends. Unquestionably every war vessel should be fitted with an armoured refuge for the wounded and also with adequate passages leading to it from all parts.

GALLANTRY OF MEDICAL OFFICERS.

It has frequently been our gratifying privilege during the present war in South Africa to call attention to the gallant and self-sacrificing way in which medical officers have performed their duties. In his despatch describing the engagement which took place on April 7th last at Tweebosch in the Lichtenburg district General Lord Methuen states that Colonel E. Townsend, C.B., C.M.G., R.A.M.C., the principal medical officer of his (Lord Methuen's) force, remained in the fighting line until he had received three wounds. "He has from the commencement of the campaign always acted most gallantly." And in the same despatch it is further stated that Civil Surgeon Prentice, with the rear-guard, and Captain H. S. Thurston, R.A.M.C., with the guns, continued to afford surgical aid to the wounded throughout the engagement. Considering how fierce the fighting was and how heroic was the stand made on that occasion by detachments of the Northumberland Fusiliers and Loyal North Lancashire Regiment and a section of a field battery of Royal Artillery some estimate may be formed of what this meant.

ROYAL NAVY MEDICAL SERVICE REGULATIONS.

A new Order in Council dated March 24th has been issued dealing with the regulations for the entry of candidates for commissions in the Medical Department of the Royal Navy and with the regulations as to medical officers.

A Memorandum dated War Office, April 15th, 1902, states that the undermentioned officers resign their commissions and receive new commissions subject to the provisions of the Militia and Yeomanry Act, 1901, each retaining his present rank and seniority, viz.:—Montgomeryshire: Surgeon-Lieutenant F. E. Marston. North Somerset: Surgeon-Lieutenant-Colonel J. Saville.

Colonel J. S. Wilkin, *D.S.O.*, *I.M.S.*, has been specially deputed to proceed to South Africa to supervise the concentration camps in the Transvaal and Orange River Colony.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin*: Dr. Albert Hoffa of Würzburg has been appointed Extraordinary Professor of Surgery in succession to the late Dr. Wolff.—*Genoa*: Dr. Ambrogio Cuneo of Rome has been recognised as *privat-docent* of Surgical Anatomy and Operative Medicine.—*Giessen*: The chair of Gynæcology having been declined by Professor von Herff of Basle, to whom it was first offered, has been accepted by Dr. Pfannenstiel of Breslau.—*Göttingen*: Dr. Jenkel has been recognised as *privat-docent* of Surgery.—*Gratz*: Dr. Rille of Innsbruck has been offered the chair of Dermatology vacated by the death of Dr. Jarisch.—*Halle*: Dr. Wullstein has been recognised as *privat-docent* of Surgery.—*Jena*: Dr. F. Lommel of Erlangen has been recognised as *privat-docent* of Dermatology.—*Naples*: Dr. D. de Berardinis has been recognised as *privat-docent* of Ophthalmology.—*Pisa*: Dr. Pasquale Sfameni has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Prague (Bohemian University)*: Dr. Ottokar Srdinko has been recognised as *privat-docent* of Histology and Embryology, Dr. Ottokar Kose as *privat-docent* of Medicine, and Dr. Wenzel Pitha as *privat-docent* of Midwifery and Gynæcology.—*Rome*: Dr. V. Marzone has been recognised as *privat-docent* of Anatomy.—*Vienna*: Dr. Riehl, Professor in the University of Leipsic and formerly *privat-docent* in Vienna, has been appointed to succeed the late Dr. Kaposi as Professor of Dermatology. Dr. Arthur Schattenfroh has been promoted to an Extraordinary Professorship of Hygiene, Dr. Emil Fronz to an Extraordinary Professorship of Children's Diseases, Dr. Mannaberg to an Extraordinary Professorship of Medicine, and Dr. S. Freud to an Extraordinary Professorship of Nervous Diseases.

Correspondence.

"Audi alteram partem."

THE OBSTETRICIAN—PHYSICIAN OR SURGEON?

To the Editors of THE LANCET.

SIRS,—Under the above heading an annotation appeared in THE LANCET of April 5th, p. 979, and as I am the physician referred to I trust that you will, in common fairness to myself, allow this letter to appear in THE LANCET.

You make various statements which are described as "facts." On the whole the case is fairly stated, as far as it goes, but that I was "remonstrated with by the senior surgeon" is untrue. The real facts of the case are as follows and I defy the senior surgeon or anyone else to prove otherwise. The Lincoln County Hospital has for its staff two consulting surgeons (who have no beds in the hospital), two physicians, and four surgeons. Each member of the staff is an ordinary general practitioner; there is no gynæcologist appointed. The present senior physician and my predecessor were appointed to the staff many years ago when gynæcology was little known as an art and abdominal section was considered an almost unwarrantable proceeding. Both these physicians took under their care from time to time gynæcological cases and advised as to treatment which was often followed out by the resident medical officer. I do not believe that they ever performed even a minor operation, such as curettage, in the hospital, but the patients were theirs and they therefore were responsible for the treatment. Immediately after my appointment two years ago I undertook gynæcological work and have treated my cases, no matter what the nature of the disease, in my own way. In those two years I have done as much gynæcological work as any other member of the staff and not until a few weeks ago has a single word of disapproval been addressed to me. I do not think that your statement that "sundry gynæcological cases having been admitted under his care" fully described the position.

Curiously enough, not until quite recently did I treat a case which in my opinion required a major operation and then five cases were admitted almost simultaneously. Three required abdominal section and two vaginal hysterectomy. The usual written notice was delivered to each member of the staff the day prior to that fixed by me for an abdominal section and no objections were raised—although ample time was given—until the patient was on the table in the operating-room and the anæsthetic was about to be administered. At this most inopportune moment two of the surgeons entered and protested against my operating and stated that they would appeal to the weekly board. No right-minded man would surely expect me to put off this operation, but as the surgeons had now raised objections, and *for the first time since my appointment*, I postponed two operations which I had decided to do two days afterwards in deference to their objection. A memorial, signed by all the members of the staff excepting the senior surgeon, who was absent on holiday, and myself, was presented to the weekly board—who are practically the board of managers—asking for an injunction to prohibit me from doing any gynæcological work. The members of the staff are all members of this board of management and four surgeons and two physicians were present at the meeting. Without any dissenting motion the board decided that physicians could treat gynæcological cases by operation or otherwise and there evidently the matter ended.

At my future operations—one a hysterectomy and the other an abdominal section—the three acting surgeons kindly assisted me and in every way aided me by their presence and help and by their so doing surely acknowledged their willingness to accept the position as laid down by the board of managers. On the return of the absent surgeon he addressed a letter to the managers asking for an explanation of their decision and the reply he received was even stronger than the wording of the original agreement and pointed out to him very clearly that I could perform any gynæcological operation. Not content with this decision of the board, whose verdict and opinion the surgeons had sought, the senior surgeon called a meeting of the staff, which all the members except myself attended, and passed a remarkable resolution to the effect that they would not assist me at any operation or take any responsibility for such work.

Now let me sum up the facts. The weekly board includes the staff. The staff—excepting myself—appeal to this board for a decision. They get such a decision and because they do not approve of the verdict they decide to boycott me—because, I presume, I act according to the rules laid down. There is no mention of any appeal to a quarterly meeting of the governors in the minutes of the meeting alluded to. This conduct seems to me to be somewhat illogical. After the decision the surgeons who were present assisted me and only after the arrival home of the senior surgeon do they change their attitude and frame this remarkable minute and decide upon an equally remarkable course.

I have been compelled to state the case fully and for the length of this letter I must apologise. I have no wish to enter into any "newspaper controversy." I decline to do so. I agree with you that no hard-and-fast rule can be drawn between the gynæcological physician and surgeon. In nearly every large hospital in London the gynæcologist is a physician and does his own operative work.

I have never objected to the surgeons of our hospital treating these cases as they think fit. I desire to live and let live and to do this successfully the less we interfere with our neighbours the more likely are we to attain our object.

I am, Sirs, yours faithfully,
J. STITT THOMSON, M.D. St. And., F.R.C.P., F.R.C.S. Edin.,
Physician to Lincoln County Hospital, &c.
April 9th, 1902.

PS.—Since the above was written a meeting of the quarterly board has been held (at which all the members of the staff were present) and by a majority the decision of the weekly board was upheld. J. S. T.

THE MOST CONVENIENT SITE FOR RE-VACCINATION IN THE MEDICAL MAN.

To the Editors of THE LANCET.

SIRS,—I lately revaccinated myself. Not having been revaccinated for 25 years it naturally "took" in a very vigorous manner. On the evening of the third day my temperature rose to 101° F. and the two subsequent days to a few points over 100°. There were three large pocks which were surrounded by a wide area of inflammation. This case, therefore, seems to me to be a particularly fitting one for testing the practical value of the position I chose for revaccination, as indicative of the best available spot on the body for revaccination in the case of the general medical practitioner. The site I selected was the space over the lower part of the sternum, between the breasts, the centre of the area being a point on the horizontal nipple-line, midway between the two nipples. The reasons why I chose this position were as follows.

Firstly, it was a most convenient place for self-revaccination. This point, of course, particularly applies to country practitioners and to such of these especially who are either "unopposed" or "uncomfortably opposed," or in any other way unable to get a professional brother to perform the little operation. I myself found it fairly easy to do it in this position without the help of a looking-glass, but to such as are somewhat short-necked or unsupple it can be readily done with the kindly aid of a mirror.

Secondly, I was afraid if my revaccination were going "to take," in what we euphemistically tell our patients, "in a splendid manner," I might be temporarily partially disabled from doing my work. As a country practitioner is essentially a "chirurgeon" in its full etymological significance this point was an important one. He has no limbs to spare even for partial disablement and a sacrifice of any one of these may entail an inability to perform a highly-skilled and urgently called for professional piece of work.

Thirdly, it is one of the most sheltered spots on the body. Lying as it does between the slightly protruding male breasts it is afforded protection from bumps and jars and, unlike the usual position on the outer surface of the upper part of the arm, it is not exposed to knocks sustained by self-forgetfulness or to the jostling citizen who cannot be expected to know that the man he has just elbowed his way against has a very tender spot that he treats with much sanctity.

Fourthly, I thought there would be much less liability to get axillary glandular pain and swelling. When the site chosen is between the breasts the area of absorption of inflammatory products has its drainage area doubled. Both sets of axillary glands now receive the irritating products of inflammation instead of its being concentrated on the one axilla, as it is when the vaccination is performed in the usual place. There seemed to me, therefore, much less likelihood of glandular swelling

Summing up, then, I may say that all my surmises in my own case proved correct. Although the case was a severe one, both locally and constitutionally, I had the perfectly free use of my arms all the time and not the slightest inconvenience in any way regarding this most important point. I had no axillary glandular pain or swelling, which I should undoubtedly have had had I been revaccinated in the usual place. I had not a single bump or jar, which few people, I think, can say who have been revaccinated with any great effect on the outer surface of the arm

Two more points may be incidentally mentioned. The position chosen is above the place one is naturally inclined to rest against the writing-desk when dealing with professional correspondence, and, lastly, one may turn over in one's sleep from one side to the other without any vague feelings of misgiving that one will have to pay dearly for one's hoped-for increased comfort.

I am, Sirs, yours faithfully,
T WILSON PARRY, M.A., M.B Cantab, &c.

Youlgreave, April 12th, 1902.

THE PLUMBERS' REGISTRATION BILL

To the Editors of THE LANCET.

SIRS,—The valuable special article in THE LANCET of March 29th last, page 901, as to the passing through the House of Lords of the Plumbers' Registration Bill and the probable opposition it may receive from those who think that if the plumber is rendered responsible to his fellow man for the reliability of his work it will be impossible for the oppositionists to undertake plumbers' work in the future puts the whole facts very clearly I sincerely trust that it may be read and digested by every Member of the House of Commons, and should be glad if it were possible that every Member could be likewise informed of the fact that until the plumber is made *responsible by registration it is hopeless to expect that reliable sanitary work can ever be thoroughly* carried out, notwithstanding by-laws, rules, regulations, patents, fads and fancies, past, present, and future. In connexion with registration the present system of training plumbers must be improved. At present it is most unsatisfactory as a whole, the so-called technical teaching being very hollow in its afterwards practical results, and the course so persistently followed by the Worshipful Company of Plumbers should be supported and followed The Bill has the hearty support of all good master and operative plumbers who are anxious to be placed in a true and reliable position and that position to be known, their motto being that of the Worshipful Company of their craft. I am, Sirs, yours faithfully,

Ebury-street, S W, April 7th, 1902. D T BOSTEL, Sen.

A CASE OF NUTMEG POISONING

To the Editors of THE LANCET

SIRS,—Mr Robert A. Pitter reports an interesting case of poisoning by nutmeg in THE LANCET of April 12th, p. 1035, and asks for information as to other cases. He will find abstract reports of several cases in "Forensic Medicine and Toxicology," by Dr J Dixon Mann, published by Messrs. Charles Griffin and Co Limited, price 21s

I am, Sirs, yours faithfully,
ANTONY ROCHE, M R C P Irel,
Professor of Medical Jurisprudence, Catholic University

Dublin April 12th, 1902.

THE NOTIFICATION OF PHTHISIS —The Knutsford, Middlewich, Winsford, and Biddulph Urban and the Bucklow Rural Districts have practically adopted the voluntary notification of phthisis at the usual fee per case. But the results are not promising In the whole combined district but six cases have been notified and the majority of these were near to death at the time when the information was received. Certainly, as Mr T W. H. Garstang the medical officer of health of the districts, observes, notification has not been received favourably in this locality

THE MEDICAL CONGRESS OF AUSTRALASIA

(FROM OUR OWN CORRESPONDENT IN AUSTRALIA.)

THE sixth session of the Intercolonial Medical Congress of Australasia was held at Hobart from Feb 17th to 22nd. The first business was to elect a President owing to the sad death of Mr R. S Bright who had been appointed to that position at the last session in Brisbane The Executive Committee had selected the Hon. G H. Butler, M L.C, for the honour, and after the report of the committee had been read the selection of Mr BUTLER was confirmed by the Congress and he took the presidential chair A vote of condolence with Mrs. Bright was unanimously passed in silence, all the members upstanding

In the evening the Congress was formally opened by His Excellency Sir H HAVELOCK, Governor of Tasmania, who also offered a hearty welcome to Tasmania to the visitors from other States, as did the Premier of Tasmania and the Mayor of Hobart. The PRESIDENT, owing to the shortness of time at his disposal, omitted the usual lengthy address but shortly welcomed the members and then referred in feeling terms to the deaths of Mr Bright, Sir James Agnew, M D (a vice-patron), Mr J G Johnson (one of the sectional secretaries), Dr E. W Way of Adelaide (a vice president), and the Australian members of the Army Medical Corps who had died in South Africa. Mention was made of the work of the Congress, especially the discussion on Cancer, which it was hoped would arouse general interest on the subject and give a basis for further investigation, but the President cautioned members not to be hasty in arriving at any definite conclusions. Other subjects on which it was hoped that some expression of opinion might be given were the Responsibilities of the States Governments to provide Sanatoriums for the Open air Treatment of Consumption, a Uniform System of Compulsory Vaccination; Quarantine Regulations, and the Training of Medical Students and Practitioners in Medical Ethics It was advised that an Ethical Section should be formed in the Congress, as suggested by the Western Australian Branch of the British Medical Association. The Congress would also have to consider the advisability of changing its name and of appointing a permanent executive committee with representatives in each State. With regard to these suggestions, on the final day of meeting it was decided that the name should be changed to "The Australasian Medical Congress," but no alteration was made in the constitution The Congress also adopted the following motions which were brought up by the Public Health Section:—

That vaccination should be uniformly enforced in all the States with the view to an early alteration of the existing quarantine arrangements and that the Federal and State Parliaments be requested to institute the necessary legislation to give effect to this resolution

That in the opinion of this section, in consequence of the prevalence of water-borne diseases in campaigns, instruction in hygiene, including the sterilisation of drinking water, should form part of the field training of the soldiers as far as practicable the drinking water supplied to the soldiers should be sterilised before issue.

That in the opinion of this Congress steps should be taken by the States of the Commonwealth and New Zealand to unify the Public Health Acts throughout Australasia.

That the term "pestis minor" should not be applied to non plague cases.

A motion regarding sanatoriums for tuberculosis was proposed but was not carried, difference of opinion existing as to what should be done, especially as to whether sanatoriums should be established and controlled by Government.

It is impossible to give a detailed account of all the work done in the various sections In Medicine the President of the section, Dr JAMES JAMIESON (Melbourne), gave a very interesting and thoughtful address, chiefly on the significance of the term "cure" in medicine He traced the history of medicine to a considerable extent from the days of superstitious belief in the infallibility of drugs through the period of scepticism, to the modern and scientific methods of guiding the natural process and influencing and controlling it, as by producing immunity and by serum- and organo-therapy He observed that nothing was more dangerous and more unscientific than to use powerful drugs for the relief of symptoms "causal conditions must be discovered and the causes removed or there could be no cure." This was illustrated by the treatment of pyrexia which might be part of nature's curative effort After a somewhat grimly humorous tilt at surgery and its advances and its smaller "cures" by removal of organs and structures which were necessary to the well-being of the patient, he concluded by saying that practitioners entered on the new century with the hope and expectation of triumphs greater than those of the past and by asserting that they could now effect genuine cures by *removing causes of disease*, killing or expelling parasites, putting an end to sources of irritation, and by counteracting and getting rid of poisons which had entered the body or had been produced within it.—Dr. W. C. WILKINSON (Sydney) read a long paper advocating the Use of Tuberculin as a Remedy for Pulmonary Tuberculosis.—The members of the section did not agree with his views and said that their experience of the remedy was unfavourable.—Mr. W. T. HAYWARD (Adelaide) read papers on Empyema and on Enlarged Bronchial Glands in Children.—Dr. JARVIE HOOD (Sydney) discussed the recent epidemic of Cerebro-Spinal Meningitis.—Dr. SYDNEY JONES, sen. (Sydney), read a paper on the Serum Diagnosis of Disease.—Dr. G. H. HOGG (Launceston) gave an account of the Aboriginal Medicine of Tasmania. Bleeding was stopped by clay and leaves, and incisions and scarifications were in much favour to let out the pain or disease. Massage was employed and the application of cold by compresses was used to relieve headache and other pains. The usual treatment for all skin diseases was for the patient to wallow in wood ashes. Rheumatism was common and was treated by incision and rubbing in mutton-bird oil. The use of charms made of the bones of the dead was common, both as preventives and as cures. Before European colonisation the aborigines appeared to have been very healthy but afterwards lung diseases, especially phthisis, and syphilis became common and were the chief cause of their extermination.—An important paper was read by Dr. F. GOLDSMITH (Queensland) on the Necessity for Education in Tropical Medicine in Australia He pointed out that there were large centres of population, such as Rockhampton, Townsville, Cooktown, Cairns, and Charters Towers, within the tropical zone where such diseases as malaria, dysentery, ankylostomiasis, beri-beri, filariasis, leprosy, dengue, plague, &c., existed in either endemic or epidemic form. The various States were in daily communication with India, China, and the Pacific Islands, from which tropical diseases were introduced, and the outbreak of plague was still in evidence. He strongly advocated the providing of a school of tropical medicine in Australia.—As a result of this paper a committee was appointed which reported as follows:—

> The committee consider it desirable that a school of tropical medicine and research should be established for the scientific and systematic investigation of tropical diseases in Australia, and to this end they recommend the following: 1. That Brisbane would be the most suitable place to carry out such investigations. 2. That the proposed school should be established on lines similar to those of the school for tropical medicine in London. 3. That the Right Hon. the Premier of the Commonwealth and the Premiers of the various States should be officially approached by the executive of this Congress for grants to enable such an institution to proceed with its work, and that the Right Hon. the Secretary of State for the Colonies and Dr. Patrick Manson (the head of the School of Tropical Medicine in London) be communicated with on the subject. 4. The section recommends the Congress to appoint Dr. Goldsmith as its representative in England.

In the Surgical Section Mr. L. E. BARNETT (Dunedin), the President, delivered an admirable address, practical and yet often eloquent in diction. He took the opportunity afforded by the presidential Address in Medicine to point out that advances into regions previously held sacred to the physician had been the characteristic of latter-day surgery, and where medicine failed surgery had come to the rescue. To its credit stood hundreds of operative procedures established by the experiences of physicians as well as of surgeons as the best and safest cures for the diseased conditions concerned Mr. Barnett then mentioned many of these in detail. Referring to anæsthesia he emphatically declared that there were far too many deaths under chloroform which was so frequently the selected anæsthetic in Australasia. Chloroform administered by an expert anæsthetist was probably safe enough and was simpler and pleasanter to administer than ether, but expert anæsthetists were few and far between. Now, to the average man he made bold to say: "Learn to give ether, and give it freely, and give it often. Follow the lead of America and reserve chloroform for the special cases." Then there would not be so many inquests and patients would not have such a dread of going under an anæsthetic. Appreciative reference was made to the debt which modern surgery owed to bacteriology and he strongly advocated aseptic as opposed to antiseptic methods. "It did harm rather than good to swab and douche healthy living tissues with antiseptics." In regard to some details of surgical technique he thought the extreme value of saline enemata and saline transfusion in averting and combating shock and the use of the Trendelenburg position were not sufficiently appreciated by general surgeons, though much used by gynæcologists. Sir Felix Semon's strictures on over-operating by specialists were mentioned and he (Mr. Barnett) was afraid that the same might be said of general surgeons, and it must be admitted that there were too many who degraded the science and art of surgery into a highly lucrative craft. Not only had modern surgery introduced a multiplicity of operations but also of operators. The success rendered possible by asepsis tempted too many men to become operators who had not received a sufficient training. All general practitioners ought to have sufficient knowledge of the general principles of surgery and aseptic technique to perform imperative surgery when the services of a skilled surgeon could not be immediately obtained. To save life the general practitioner should be prepared to operate for strangulated hernia, appendical abscess, &c., but not in the same way to undertake lightly the operation of radical cure or appendicectomy when the patient could be sent to a skilled operator. He concluded with a fine peroration on the work of the Australian surgeons in the South African campaign.—In the sectional work papers on the Treatment of Prostatic Enlargement were read by Mr. G. A. SYME (Melbourne) and Dr. H. V. C. HINDER (Sydney), both advocating total prostatectomy in the early stages of the disease for most cases, a procedure advised by the former in 1897. Operation should be performed as soon as the use of a catheter became necessary.—Dr. W. MOORE (Melbourne) discussed the Treatment of the Appendix in cases of Abscess and advised its removal, quoting cases in illustration.—Dr. W. KENT HUGHES (Melbourne) read a paper on the Treatment of Deformities following Infantile Paralysis, advocating free tenotomies and transplantation of tendons.—One of the most original and ingenious papers contributed to the Congress was that by Mr. R. HAMILTON RUSSELL (Melbourne) on the Congenital Factor in Hernia Mr. Russell had formerly maintained that all cases of inguinal hernia were congenital and due to the existence of a preformed sac. He now maintained that all forms of hernia—femoral, obturator, &c.—were also due to a congenital condition, and he elaborated a most ingenious hypothesis to account for the formation of the sac by assuming a protrusion of the inner layer of the mesoderm into the budding lower limb at the fourth week of fœtal development, and also expressed the belief that it was the existence of this preformed sac and its relation to the developing blood-vessels of the lower limb, especially the branches of the common femoral artery, that determined the course taken by a femoral hernia.—Dr. W. A. WOOD (Melbourne) discussed the Treatment of Congenital Dislocation of the Hip and narrated five cases treated by the Lorenz method, three with marked success.—Dr. J. B. NASH (Sydney) read a paper entitled "Some Observations in Relation to Nephrectomy," and Dr. ALAN MACKAY (Melbourne) contributed a practical paper on the Use of the Double Thomas's Splint in Hip Disease.

In the section of Midwifery and Gynæcology Dr. RALPH WORRALL of Sydney, the President, took as the subject of his address the Advances on the Subject since the First Session of the Congress. In midwifery the greatest advances had been in the adoption of Cæsarean section instead of destruction of the child, the re-introduction of symphysiotomy, the aseptic conduct of labour, especially the avoidance of vaginal examinations and douches, and the management of the third stage by waiting for the placenta to be naturally expelled. One of the most marked advances was in the early recognition and treatment of extra-uterine gestation. In gynæcology the treatment of uterine deviations had been completely changed—the pessary had become obsolete and operative measures, especially the Alexander-Adams operation, the rule. In pelvic surgery, and especially the treatment of fibro-myoma, the greatest advance was seen in the methods of restraining hæmorrhage, for which the profession in Australasia were greatly indebted to Professor A. Watson of Adelaide who anticipated the methods of Howard Kelly and whose procedure was even better than Kelly's.—A feature of the addresses in medicine, surgery, and gynæcology, delivered by leaders of their professions in three different States, was a marked tendency to object to the encroachment of others in what they regarded as their own sphere of work. Dr. Jamieson gibed at the surgeons, Mr Barnett returned the compliment and further objected to general practitioners doing surgery, and finally Dr Worrall lodged a very strong protest against general surgeons doing gynæcology —In the sectional work Professor WATSON (Adelaide) read a paper on Some Points in Connexion with the Gynæcological Surgery of the Round and Broad Ligaments. It was chiefly anatomical, with reference to the blood supply of the different pelvic organs and the best means of isolating and separately controlling the various vessels—in fact, very similar to his paper on the subject at the previous congress —Dr G R ADAM (Melbourne) opened a discussion on the Treatment of Chronic Pelvic Suppuration —Dr H O COWEN (Eaglehawk Victoria) read a paper on an Analysis of 700 Consecutive Confinements in Private Practice, a rejoinder to a paper which had been read by Dr Purdy at the Brisbane Congress and a plea for "standard details" on midwifery, and leaving "the shifting sands of individual experiment for the sure standing ground of collective experience" The minimum of interference with nature's processes, in the way of examination, douching, forceps or expression of placenta, was the main contention of the paper, which, with a paper by Dr ALAN MACKAY on Symphysiotomy, was specially discussed.

Public attention at medical congresses chiefly concentrates itself on the section of Public Health, the work in which is most fully reported in the public press. Dr T CHERRY (Melbourne), the President, gave a very comprehensive and up-to-date address on the Etiology of Typhoid Fever He detailed the results of observations on the typhoid bacillus and the various forms of colon bacilli and their separate and conjoined effects and summarised the most recent literature on the methods of contagion and spread of the disease, especially drawing attention to the probable share of flies and dust in this connexion. He concluded an admirable address by stating that many mild cases of fever were often classed as slight attacks of typhoid fever and might serve to distribute contagion Typhoid fever itself might be a composite disease or a series of diseases caused by a closely allied organism. Typhoid fever at once disappeared from the community with the introduction of a proper system of the disposal of excrement and household refuse in towns. The disease was spread chiefly by the contamination of water, milk, and articles of food. In hot countries at least flies and dust had a considerable share in bringing about this contamination The length of time during which the bacilli could exist outside the body was unknown There was evidence to show that contagion hung about old cesspits and contaminated soil for several years.—In the work of the section Mr T M KENDALL (Sydney) read a paper on Sewage Disposal, detailing the results at Sydney where various systems were employed discharge into the ocean land filtration lime precipitation, the Scott-Moncrieff system and the septic tank method. After being screened in this manner the sewage fell into a septic tank, constructed on the Dortmund principle, and thence it was sent laterally into a Scott Moncrieff cultivation tank, through which it passed by upward filtrations, to be distributed over a percolating filter, composed of coke or coal The distribution was so arranged that a definite quantity of sewage was applied to every square yard of the filter in an intermittent manner and the filter itself was composed of coke stacked without any retaining wall —Dr JAMES JAMIESON read a paper on a Milk Epidemic of Typhoid Fever, illustrating the Duration of Infectivity He showed that typhoid germs might lodge in the body of a patient for a long period after recovery and that the disease was more liable to be spread from contaminated urine than from fæcal discharges, even after apparent convalescence. He detailed a series of typhoid fever cases occurring among customers of a dairy in Melbourne. During the time that the proprietor was absent suffering from fever the milk was all right, but upon his returning to work as cured the milk gave rise to a series of typhoid fever cases in instances where the customers required fresh cows milk, not sterilised. The man, it was assumed, distributed the infection through his hands in milking the cows The duration of the period of infectivity pointed to three months.—Dr CHERRY gave an address on Pseudo-Tuberculosis (Caseous Lymphatic Glands) in Sheep. Probably the inoculation took place from cuts and scratches at shearing time. The disease was spreading and was important because of the relation of the micro-organisms to that of glanders. Should the horse become infected it would be exceedingly difficult to diagnose it from glanders, and unless care was taken it might be confused with the plague bacilli, which it was not unlike.—Dr W EAMES (Newcastle, New South Wales) read a paper on Diseases in War, pointing out that the greatest mortality was from water borne diseases. He advocated training the soldiers in sanitary precautions and especially in the methods of sterilising drinking water

In the section for Diseases of the Eye, Ear, and Throat Dr T K. HAMILTON (Adelaide) the President, gave a short address on the Progress of these Special Departments. Specific diseases of the eye were discussed at some length, as was the treatment of middle-ear suppuration and sinus suppuration Two evening meetings of the whole Congress were held to discuss the subject of Cancer —Professor H. B. ALLEN (Melbourne) opened with a most elaborate paper, giving an exhaustive review of the recent literature and experiments on the nature and parasitic origin of cancer He observed that in its predilection for people in declining years it was unlike most parasitic diseases and also in its mode of dissemination and stated his own opinion decidedly that cancer was not a parasitic affection He also thought that the tendency for innocent tumours to become malignant was much exaggerated. As regarded the influence of race, the savage races of mankind suffered much less than did the civilised He considered that the influence of local irritation in favouring the evolution of cancer was beyond question Most carefully compiled statistics were given of the prevalence of cancer in Australasia. During the first five years 6 8 per cent. of the deaths so recorded were due to cancer, during the second five years 6·9 per cent., during the third, 9 1 per cent., during the fourth, 10 2 per cent., and during the fifth, 10 4 per cent Allowance must be made, in the first place, for increase of population, and it was then found that the Australasian death rate from cancer for every 10 000 living had risen in the last 30 years for all persons from 2 75 to 5·72, for males from 2·65 to 5·91, for females from 2 86 to 5 50, or, if they took 100 as the standard 30 years ago, to 223 for males and to 192 for females. In this short period, therefore the recorded cancer rates per 10 000 living had somewhat more than doubled in males and somewhat less than doubled in females The female rate, which was the higher, had become substantially the lower In Australasia there had been a striking increase in the number of old people, of persons in the cancer period, both an absolute increase and an increase in proportion to the whole population. The old men had nearly doubled in numbers in relation to the whole community, while the old women had far more than doubled A large part of the increase in cancer was explained in this simple way Not only was the death rate from cancer in persons under 25 years of age very small, but since 1880 it showed no increase. The rate for cancer in children and young people was not increasing Professor Allen's general conclusion was as follows While I am not prepared absolutely to deny that there has been any increase in the prevalence of cancer I can state positively that malignant tumours in young people show no recent sign of increase, that among the external cancers which are easily recognised those of the face and lip in males appear to be less frequent than formerly, while cancer of the breast in women has also decreased, that uterine cancer has only slightly increased the rates for women under 55 being lower than they were 30 years ago that the apparent increase of cancer is most marked in old people and particularly in women of 75 and upwards, and I am strongly of opinion that most of this apparent increase is fictitious, being due partly to changes in the age distribution of the population and partly to more regular medical examination better diagnosis, and more explicit registration'—Dr J C VERCO (Adelaide) read a paper on the Cancer Statistics of South Australia which confirmed those of Professor Allen —Dr WILKINSON (Sydney) spoke on the Etiology of Cancer, upholding the parasitic view —Mr F D BIRD (Melbourne) contributed a paper on the General Results of Radical Operations, maintaining that while many cases could be said to be unpromising none could be called hopeless.—Dr SYDNEY JAMIESON (Sydney) discussed the Influence of Injury Irritation, and Preceding Inflammation on the Production of Cancer and held that it was considerable.—Owing to the time occupied in reading these papers none was left for general discussion.

An account of the Congress would be incomplete without reference to the hospitalities showered on the members The President and Mrs. Butler entertained the members at a garden party and at a reception. The President also gave a dinner to the leading officers of the Congress. The Governor of Tasmania and Lady Havelock gave a garden party and the Premier and Mrs. Lewis held a reception. The Mayor entertained the Congress with an excursion to New Norfolk and the Salmon Ponds. The Union Steamship Company provided a trip down the D'Entrecasteaux Channel, and Senator and Mrs. Macfarlane gave a garden party. It was decided to hold the next session at Adelaide and Dr. E. C. Stirling was elected President.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Success of the Dufferin Fund.—The Plague Epidemic.—Refusal of Commissions in the Indian Medical Service.—Increase of the Indian Army Nursing Service.—Improvements in Rangoon.

A REPORT recently issued shows that the work of the Dufferin Fund has become one of great magnitude. No less than 1,750,000 patients received relief at the hands of its female medical practitioners last year and it is of interest to record that Pardah Nashin women are being increasingly attended to. There are now 40 lady practitioners holding qualifications from the United Kingdom and 82 others who possess Indian licences. Amongst its own hospitals there were 7516 in-patients and 231,427 out-patients, the rest of the patients going to affiliated hospitals. The work of the association offers a training to nearly 500 students and a large number of women are being educated as midwives. The funds are also flourishing, for including the six and half lakhs of rupees collected by Lady Curzon the total investments of the fund amount to 31 lakhs.

The plague continues to increase in the Punjab but shows some signs of abatement elsewhere. Both in Bombay city and in Calcutta there has been a decline. In the Punjab the course of the disease is instructive. Here it first broke out in 1897 and for three years kept in the limits of two districts. There were 3500 cases in the first year, 423 in the second, and 859 in the third. In 1900-91 it began to spread and for that year 10,000 cases were reported. Since then the previous precautions have been abandoned, or, at any rate, they have not been enforced, and the disease has advanced rapidly. In the past five months 90,000 cases have been recorded and now eight districts and five native States are affected. The native press was formerly very bitter against the Government for enforcing preventive measures but now it is blaming the Government for not pressing them. The results of inoculation for plague among the Parsi community in Bombay speak well in favour of the process. During 42 months there were 1033 deaths among the uninoculated section and 51 amongst the inoculated. If the latter had suffered in the same ratio there would have been 170 deaths; so it is estimated that inoculation saves about 70 per cent. of those who might have died.

It appears that several of the plague medical officers who were offered commissions in the Indian Medical Service have for various reasons been unable to accept them. As the treatment of the medical officers sent out to India for plague duty has not been marked by excessive liberality it would be interesting to know what hindrances were placed in the way of the officers accepting these commissions.

In the programme of improvement for the army in India provision is made for an increase in the Army Nursing Service. The increase is to amount to 39 but it will be limited next year to three superintendents and 13 nursing sisters.

The movement for improving some of the worst quarters of the native parts of many Indian cities is extending and Rangoon is now brought under its influence. The Government of India has approved of the scheme concerning the Sadr Bazaar. The most insanitary portions will be entirely demolished and its inhabitants will be removed to another part of the city. The place was not only a nuisance but a serious source of danger to the public. Work of a similar kind is going on in Bombay city and in Calcutta. The danger seems to be that in some places improvements will be permitted rather than the enforcement of complete demolition and reconstruction. A mild policy in these matters will only lay up troubles for the future.

March 26th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

A Liverpool Private Hospital and the Sale of Throat Pastilles.

IN the Chancery Court of Lancashire at St. George's Hall last week, before the Vice-Chancellor, Messrs. Evans, Sons, and Co., wholesale druggists of Liverpool, claimed to set aside an agreement with William Alfred Jones (formerly export manager in their employ) in respect to the manufacture and sale of throat pastilles. The plaintiffs (Messrs. Evans, Sons, and Co.) also claimed damages and an account of all moneys received by the defendant (William Alfred Jones) under the said agreement and prior thereto; and in particular such portion thereof as was intrusted to the defendant on behalf of the Liverpool Hospital for Diseases of the Throat, Nose, and Ear; and also payment to the plaintiffs of the amount not properly applied. The defence was a denial of the allegations made by the plaintiffs and the defendant counter-claimed for a declaration that plaintiffs were no longer entitled to manufacture and to sell the pastilles and the delivery up to him of the formula and various documents, an injunction against the plaintiffs from advertising, manufacturing, or selling the pastilles, and payment to defendant of £220 10*s.* 2*d.* due from plaintiffs to him. Mr. Maberley, in opening the case for the plaintiffs, said that the defendant was in the employ of the plaintiffs as export manager for 35 years and in 1893, while defendant was honorary secretary and treasurer of the Throat Hospital, a private institution in Oxford-street belonging to Mr. John Bark, M.R.C.S. Eng., in which patients were treated gratis, he was given some lozenges by Mr. Bark for the use of his wife who was suffering from an affection of the throat. At defendant's request Mr. Bark wrote out a formula for less costly lozenges which defendant took to the plaintiffs. He suggested that they should manufacture and sell them and that apart from the business profit a substantial portion of the proceeds should be handed over to the hospital. The plaintiffs agreed to the proposal and a royalty of 6*d.* per pound weight was fixed verbally as the amount to be devoted to the hospital. The first payment on account of the royalty was made in the year 1896 and other payments followed up to December, 1901, a list of which counsel handed in. The Vice-Chancellor said that the total was £2393 18*s.* 2*d.* In April, 1900, the defendant produced a letter from Mr. Bark in which that gentleman wrote: "I have no claim or interest in the prescription you got for me some years ago for the throat pastilles"; and following that the defendant, who described himself as sole proprietor of the formula, offered in writing an authorisation to the plaintiffs to manufacture the pastilles for sale in all parts of the world in consideration of their paying him a royalty of 6*d.* per lb. weight. On May 9th the plaintiffs wrote confirming the arrangement, adding that they understood that the royalty (as advertised by them) was largely applied by defendant for the benefit of the hospital. Afterwards the plaintiffs found that while the sales were going up by leaps and bounds the defendant was not devoting any part of the royalty, which now amounted to over £800 a year, to the hospital; and they now contended that defendant, who had ceased his connexion with the hospital, was acting merely as their agent and that they were entitled to demand that the royalty should be refunded to them in order to be handed over to the hospital. Mr. John J. Evans, senior active partner of the plaintiffs' firm, deposed that the agreement with the plaintiffs in 1893 was that the royalty of 6*d.* per pound of the pastilles should go to the hospital, of which defendant said that he was the secretary. Nothing was said about defendant retaining any part of the royalty. At Mr. Bark's request that gentleman's name was withdrawn from use. Witness, in the course of his evidence, said that he remarked to Mr. Jones that the hospital must be getting very rich owing to the large amount it was receiving. Mr. Edward Evans, jun., another member of plaintiffs' firm, deposed that the statement in the advertisements that part of the proceeds went to the hospital assisted the sale. In cross-examination witness said that it was his absolute conviction that defendant was applying the money to the hospital. He had understood that the hospital was a public institution and it was a disclosure to him to find that it was a private concern. Mr. Bark deposed that the Liverpool Throat Hospital was a private hospital in that no subscriptions were asked for from the public, but it was public inasmuch as nobody was refused whether he could pay or not. There was no committee and witness managed it. In 1892 or 1893 he became acquainted with defendant whose wife and children witness attended. He remembered giving the formula of the pastilles to Mr. Jones, but nothing was said about any benefit to the hospital or anything of that sort. About 1896 witness appointed Mr. Jones as secretary to the hospital and defendant told him on several occasions that Messrs Evans were going to give a donation to the hospital. Nothing was said about a royalty and Mr Jones never told him he was receiving anything for the hospital. Witness removed defendant from the office of secretary in September, 1900, as he was dissatisfied with the accounts and other things, and defendant assigned to him his interest in the lease of the premises The defendant claimed that the royalty was his absolutely He did not recognise the right of Mr Bark to dismiss him from the honorary treasurership. He claimed that he was still the treasurer and that therefore there was no concealment from the plaintiffs of his dismissal. Judgment was given for the plaintiffs There would be an account taken of the royalty due from the defendant and that money, together with the royalty in the plaintiffs' hands, would be paid into court where it would remain until a scheme, of which the Attorney General would have notice, had been settled for placing the hospital on a permanent basis.

April 15th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh Public Health. Examination of Pathological Products

IN THE LANCET of previous weeks reference has been made to the position of this question. It may be recalled that the examination of certain pathological products had been carried out at the laboratory of the Royal College of Physicians of Edinburgh for the public health authorities. The arrangement covered the examination of swabs from the throat in suspected diphtheria, sputum from cases of suspected tuberculosis, blood from suspected cases of enteric fever, and urine and milk for tubercle bacilli The remuneration was a small charge for each specimen examined, the total sum amounting to about £120 in the course of a year When the Usher Institute of Public Medicine was nearing completion the trustees or committee, under whose guidance the institute was planned, expressed their readiness to undertake the examination of practically all kinds of suspected material brought under the notice of the public health authorities For this purpose certain rooms in the new institute were to be set apart in accordance with the expressed desire of the donor whose name the institute bears. It was indicated also that a medical man, a trained bacteriologist, would be appointed specially for this work and that he would work under the direction of the professor of public health, who is of course, a highly trained and expert bacteriologist and who is called upon to make expert reports on matters affecting the public health in different parts of Scotland The sum suggested as suitable payment was larger than that earned by the laboratory of the Royal College of Physicians of Edinburgh, but the proposals covered a much wider range of investigation When the proposals from the trustees of the Usher Institute came before the Public Health Committee of the Edinburgh Town Council it was decided that until the town council had a laboratory and a bacteriologist of its own the arrangement with the Royal College of Physicians of Edinburgh should be maintained When this decision came up before the town council it was disapproved and upset, the council deciding in favour of transferring the work to the Usher Institute This, as was mentioned at the time, led to much heart-burning, and two meetings of the medical men of Edinburgh were called and votes were passed expressing confidence in the College laboratory and requesting that the examinations should continue to be made there. Those who were at the trouble of getting up those meetings were further at the trouble of organising an exhaustive canvass of the individual members of the profession and of getting the great majority of the local profession to sign a petition against the proposed change. A deputation also appeared before the town council with the same object in view. All this was undertaken in the expectation that the town council might reverse its decision when its own minutes came up for approval and confirmation The last vote was taken on April 9th and the minute transferring the work to the Usher Institute was confirmed by a majority of one, but a number of members absented themselves. The majority of the profession in Edinburgh have thus failed to carry their point. They felt that the town council had acted ungraciously to the College laboratory but now that their generous sentiments have had expression they will doubtless realise the value of the gift which Sir John Usher has made to the University and the city, and as there can be no question as to the efficiency of the arrangements which the University and the trustees of the institute will make it may be hoped that certain feelings which have been aroused will be allowed to subside.

University of Edinburgh · Graduation Day

The spring graduation ceremonial of the University of Edinburgh was held in the M'Ewan Hall on April 11th, when degrees were conferred in arts, science, and divinity As Sir William Muir, Principal of the University, was unable to be present owing to his recent illness, the degrees were conferred by Sir William Turner, K.C.B., senior professor Among the honorary graduates was one medical man, Sir John Batty Tuke, on whom the University conferred the degree of LL.D. A similar honour was conferred on Miss Dorothea Beale, Principal of the Ladies' College, Cheltenham The address to the graduates was delivered by Professor MacGregor of the chair of Natural Philosophy Professor MacGregor made appreciative reference to the late Professor Tait whom he had succeeded in the chair. In the course of his address he pointed out that the four main characteristics of Professor Tait's teaching were 1. His full consciousness of the evils of the system which makes examination the sole test of fitness for a degree. 2. His efforts to counteract these evils by interesting his students in the practical study of his subject and exciting in them the love of investigation for its own sake. 3. His habit of throwing his laboratory students upon their own resources and encouraging them to cultivate originating power 4. His success, notwithstanding the difficulties which the examination system and the lack of funds occasioned, in making his laboratory, by his own efforts and the enthusiasm which he was able to rouse in his students, one of the most productive laboratories in the United Kingdom Professor MacGregor then referred to the Tait Laboratory Endowment Fund as a scheme which presented the most suitable method of commemorating the great services which Professor Tait had rendered to the University, and announced that the fund had been started by an unsolicited and unexpected subscription of £1000 from a donor who did not wish his name to be announced. He felt sure that Professor Tait's old students throughout the world would be eager to raise to his memory so appropriate a memorial.

Bequest for the Chair of Bacteriology in Edinburgh University

By the will, dated Jan 5th, 1891, of the late Robert Irvine, Fellow of the Chemical Society, the testator leaves certain shares in the Christmas Island Phosphate Co., Limited, as a separate trust to be invested by his trustees in their own names until the property accumulates to the value of £25,000 or £30,000, when the trustees are to pay the sum over to the Association for the Better Endowment of the University of Edinburgh, or to such authorities in connexion with the University of Edinburgh as the trustees shall deem expedient, for the purpose of founding a professorship of bacteriology in the said University and the equipment of a class-room and laboratory for the teaching of the same and for conducting original investigation in that subject. The testator suggests that in order to promote the study of bacteriology merely nominal fees should be charged for attendance at lectures and in the laboratories The trustees under this will are Dr German Sims Woodhead, professor of pathology in the University of Cambridge; Dr David Patrick of Edinburgh, Mr David Jardine, manager of G and J Cox, Limited, Edinburgh, Mr Robert M'Vitie, biscuit manufacturer, Edinburgh, Mr William Maxwell, journalist, London, and Mr George Muro Wood, S S C., Edinburgh

St Andrews University Graduation Ceremonial.

The annual graduation ceremonial of St. Andrews University was held on April 2nd in the New Library Hall, Principal

Donaldson, Vice-chancellor of the University, presiding. Among several gentlemen who received the honorary degree of LL.D. was Sir William Turner, K.C.B., professor of anatomy in the University of Edinburgh, and President of the General Medical Council.

University of Aberdeen: Graduation Day.

Graduation day in connexion with Aberdeen University was observed on April 10th, when Lord Strathcona took farewell of the students in his capacity as Lord Rector. In the morning Lord Strathcona was entertained at breakfast by the Students' Representative Council. After the graduation ceremony the venerable Lord Rector was entertained at luncheon in the Students' Union, and in the evening, with Lady Strathcona, he attended a brilliant reception given in the Mitchell Hall by the Principal and the professors of the University. The Lord Rector's Prize in the Faculty of Medicine was awarded to Harry O. Nicholson, M.D. The following awards were also made: Fife Jamieson Memorial Gold Medal in Anatomy, Bertie R. G. Russell, Orkney; Lizars Gold Medal in Anatomy, Catherine E. Anderson, Ceylon; Keith Gold Medal in Surgery, L. D. Cruickshank, Tarves; Shepherd Gold Medal in Surgery, Alex. Callam, Aberdeen; Dr. James Anderson Gold Medal and Prize in Clinical Medicine, R. D. Keith, Turriff; Matthews Duncan Gold Medal in Obstetrics, R. D. Keith, Turriff.

Aberdeen Royal Infirmary.

Lord Mount Stephen has generously offered a capital sum sufficient to yield an annual revenue of £1000 to Aberdeen Royal Infirmary. Lately he gave £25,000 to the same institution to pay the existing debt.

Death of Alexander Macgregor, M.D. Aberd.

The death is announced, at his residence in Queen-street, Berkeley-square, London, of Dr. Alexander Macgregor who was for many years assistant to the professor of medicine in Aberdeen University as well as a prominent private practitioner.

April 15th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Death of Dr. Thomas More Madden.

I MUCH regret to announce the death of Dr. More Madden, the well-known gynæcologist and obstetric physician to the Mater Misericordiæ Hospital, which occurred on Monday last at his country residence, Tinode, co. Wicklow.

The Smyth Memorial Fund.

The balance sheet of the Smyth Memorial Fund appeared in the *Irish Times* of April 15th and affords satisfactory reading, the total sum of £7629 being highly creditable to the public spirit and philanthropy of the various districts that concerned themselves in the matter. Dublin as usual heads the list with a contribution of £3600, the commercial wealth of Belfast is represented by £1700, Londonderry generously sent £1500, while from London nearly £800 have come. The Duke of Abercorn and Dr. T. Myles, President of the Royal College of Surgeons in Ireland, are the trustees of the fund and have arranged that the interest on one half of the total sum will be paid to Mrs. Smyth during her life while the interest on the remaining half will be devoted to the maintenance of her children. The deed contains powers to utilise a proportion of the capital for the advancement in life of the children.

Meath Hospital and County Dublin Infirmary.

The annual meeting of the governors of the Meath Hospital and County Dublin Infirmary took place on April 15th, when the 148th annual report of the institution was presented. In proposing that the thanks of the meeting should be accorded to the Dublin County Council and the City of Dublin Corporation for their continued support. Sir John W. Moore alluded to the great danger of a small-pox epidemic to which the citizens were recently exposed and to the necessity for those precautions which had up to the present proved so successful. He mentioned that the late Registrar-General, Dr. Grimshaw, had calculated that the epidemic of that disease in 1872 had cost the inhabitants of Dublin between £20,000 and £30,000.

Ulster Medical Society.

The sixth meeting of the session was held in the Museum, Belfast, on April 10th, the President (Professor W. Whitla) being in the chair. Dr. A. Fullerton showed a Gall-stone of Unusual Structure; Dr. J. B. Darling read notes of a case of Cholecyst-duodenostomy; Dr. W. Donovan read notes of a case of Hodgkin's Disease; Mr Robert Campbell described a case of Colo-colostomy for Stricture of the Colon; and Dr. Darling showed a case of Skin Disease in a man, aged 80 years. In the discussion which followed these communications Dr. W. Calwell, Professor J. W. Byers, Dr. W. B. McQuitty, Mr. W. G. Mackenzie, Dr. H. L. McKisack, and the President took part.

The Education Question.

A committee of the Belfast Chamber of Commerce has been appointed to consider the desirability of having classes of the same standing as those of the Royal College of Science of Dublin established in connexion with Queen's College, Belfast. The best way to accomplish this would be to ask for a part of the annual State endowment, £30,000 per annum, which is paid to the Royal College of Science, a purely local Dublin institution, to be diverted to Belfast for scientific education.

The Royal Horticultural Society.

The Royal Horticultural Society has just presented the Veitch memorial medal to Dr. Augustine Henry, F.L.S., a native of County Derry and a former student of Queen's College, Belfast, in recognition of his great services to botany. Dr. Henry has sent home from China, to Kew and other great botanical institutions on the continent, in America, and in India, an enormous collection of plants. He has, according to Sir Thiselton Dyer, who proposed his health at a dinner given by the London Horticultural Society, given the world the first information concerning the flora of the interior of China, perhaps the richest and most beautiful now known.

The Ulster Medical Institute.

On Saturday afternoon last, in the presence of a large number of members of the medical profession, Dr. P. Redfern, late emeritus professor of anatomy and physiology in Queen's College, laid the foundation-stone of the new Ulster Medical Institute which Professor W. Whitla, the present president of the Ulster Medical Society, has in the most generous way signified his intention of erecting and equipping. The building, which will be in College-square North, Belfast, will be fitted up in the most complete manner with all necessary requisites. It will be entered by an outer porch and an inner porch leading to a large recreation hall which is divided from the library by a stone arcade filled in with glazed folding doors. These rooms cover the front portion of the ground floor, at the back of which are the staircase and private consulting-rooms with the usual accessories. The first floor is entirely occupied by the great lecture hall, above which on the top floor are a billiard-room, the librarian's quarters, a kitchen, drawing-rooms, &c. The front of the building, facing College-square North, is designed in perpendicular gothic work and presents a frontage of 45 feet to the street by about 46 feet high to the top of the parapet, with a gable in the centre, and contains many architectural features boldly and effectively treated. Every arrangement has been adopted to make the institution as perfect as possible in all its internal details. Frequent reference was made by the various speakers to the very great munificence and generosity of Professor Whitla, who by his gift of this institute, which will cost between £5000 and £6000, has done so much to provide a long-wished-for building which will be the exclusive property of the Ulster Medical Society in Belfast and the North of Ireland.

April 15th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Statistics of 100 Cases of Abortion.

AT the meeting of the Obstetrical Society which was held on March 20th Dr. Blondel read a paper embodying the results of 100 cases of abortion which had occurred in his private practice during a period of 12 years. Of all these cases not one had proved fatal, a fact which Dr. Blondel explained by saying that in private practice the medical attendant is called in by his patient at a much earlier date than that at which a hospital patient applies to the hospital Some of the cases, however, were very grave and showed signs of a general infection with commencing peritonitis. The number of grave cases was 30 in all; in six of these there was profuse hæmorrhage, in 19 the uterine adnexa were affected by inflammation, in five there was diffuse suppuration which was relieved in four cases by an opening being made through the vagina and in one case by spontaneous evacuation into the rectum. In three cases chronic salpingo-ovaritis occurred and two of these were treated without operation while one was treated by an abdominal salpingectomy. The treatment consisted in a thorough curetting first with the finger and afterwards with a curette; in swabbing out the uterus with glycerine of creasote of a strength of one in three; and in injections of tincture of iodine and in a gauze drain, the gauze being dipped in glycerine of ichthyol of a strength of one in 10 This drain was renewed every two days and when it was changed the uterus was well flushed out by means of Dr. Blondel's sound, a solution of corrosive sublimate being employed No untoward results were noted. From the clinical point of view those 100 cases of abortion were divided into eight at the third month and 92 at a later date. At the fourth month there were 59, at the fifth month 28, and at the sixth month two. The greatest number occurred between the thirteenth week and the seventeenth week. On eight occasions when Dr Blondel arrived he found abortion threatening or just begun, on 80 occasions the fœtus was already expelled, on 60 occasions the placenta was expelled as well, and on 20 occasions it was altogether, or almost completely, still within the uterus As regards the etiology among the 100 cases, eight were obviously due to syphilis and five were probably so, one was due to a carriage accident, one to malaria, and one to tuberculosis, 52 were confessedly purposely procured, and 26 had probably been so as septic infection was present. One case was due to an error in diagnosis. The 52 cases of purposely procured abortion were divided up as follows according to the statements of the patients which, however, it must be remembered, are by no means trustworthy. On 22 occasions the operator was a midwife, on two occasions a medical student, on one occasion a medical man, on one occasion a pharmacist or a pupil in pharmacy, on six occasions a "lady friend," and on one occasion the husband of the patient 19 of the patients said that they had operated on themselves in five instances by taking medicine (!) and in 14 instances by manipulation, nine times by injections of soap, three times by violent exercises, once with a knitting needle, and once with a bone knitting pin. As regarded the midwives, the patients made the following statements In three instances the name and address of the midwife had been obtained from an advertisement in a newspaper. Two midwives continued to visit the patient unknown to the medical attendant in the intervals between his visits. On 15 occasions the midwife used a steel sound and on 10 occasions a gum elastic catheter and an injection. This last method was extremely painful and on two occasions brought on an attack of syncope. In no case, even when there was no doubt that instrumental interference had been employed, did Dr. Blondel detect any wound or abrasion of the cervix enough to swear to as evidence of criminal procedure. Abortion came on generally within eight days after the operation. Two patients made two visits to two different midwives, the first having done nothing but swindle the patient. Dr. Blondel mentioned one case that he knew of in which a woman whose menses had not appeared paid a large sum of money to a woman to procure abortion for her The woman went through various complicated procedures but the patient was not pregnant at all. Dr. Blondel concluded by saying that in every case where he suspected that criminal intervention had taken place he was accustomed to disinfect the uterus thoroughly, even though no sign of sepsis was present. An unnecessary cleansing, if properly performed, did no harm even if it did no good, but if the cleansing process were put off till late the time quickly arrived when no operative measures could ward off septicæmia.

Prophylactic Injections of Anti diphtheritic Serum.

M. Netter, M. Bourges, and M Bergeron have recently made some important researches into the prophylaxis of diphtheria by injections of anti-diphtheritic serum. M Sevestre, to whom was assigned the duty of inquiring into the investigation on behalf of the Academy of Medicine, made his report at the meeting of March 18th. He agreed with the above-named three observers in being favourable to the use of the injections. He considered them to be efficacious and from the facts before him he drew the following conclusions. Preventive injections of serum have a manifest action—they immunise children exposed to the infection of diphtheria. They have up to the present never given rise to any serious consequences. At the most they produce in a certain number of cases a fleeting eruption and very rarely pains in the joints. Unfortunately, the period of immunity does not last long, only for three or four weeks at the most. In those rare cases where, despite the use of the injection, diphtheria has been contracted the attack has been very light. These injections are specially called for in families where a case of diphtheria has developed for the protection of the remainder of the family, although if the children can be kept away from the affected person and can be under the surveillance of a medical man near at hand the injections may be dispensed with in their case. Preventive injections are equally called for in circumstances where children are massed together, such as in schools or hospital wards where a case of diphtheria has occurred. Even where there is no diphtheria these injections are useful in cases of scarlet fever or measles. In the latter disease the prophylactic action of the serum seems uncertain and the injections ought to be given in increased strength and at shorter intervals than in other diseases. The injections do not do away with the necessity for other preventive measures, such as disinfection and isolation, but by their use the carrying-out of the ordinary measures is rendered easier and of more effect. The Society of Pediatrics had in 1901 passed a resolution advising the use of prophylactic injections of anti-diphtheritic serum in cases where children were massed together or were not under skilled surveillance.

Radica and Doodica.

Dr Doyen read an interesting paper before the Academy of Medicine at the meeting of April 8th upon the case of Radica and Doodica. He pointed out that it was an error to describe a xiphopagous monster as being joined by a membrane. In the case under consideration there was no supplementary tissue and that which was improperly called the membrane of union was nothing but a false pedicle produced by the dragging upon the normal tissues, the length of the pedicle increasing with the age of the monster. The formation of such monsters is explained by the simultaneous double fertilisation of one ovule; two embryos are formed side by side which are always of the same sex The two portions of the monster possess a certain individuality although their circulation is in common, a fact which is demonstrated by the use of methylene blue, an interchange of blood takes place very quickly All the time that Doodica suffered from a high temperature the temperature of Radica was also raised but only slightly. It appeared also by the great degree of feebleness exhibited by Radica, after separation, although she remained well in other respects, that she received a fair amount of arterial blood from her sister. Doodica, on the other hand, appeared to become immediately more resistant, as if she had received mainly venous blood before separation Despite the width of the uniting band there was but little blood lost during the operation The death of Doodica was solely due to the tuberculous peritonitis from which she was suffering Radica was now quite well but the lateral curvature with which she was affected, due to walking in the constrained position which the junction with Doodica necessitated, greatly impaired her powers of walking alone.

April 16th.

(FROM OUR OWN CORRESPONDENT.)

Treatment of Osteomalacia

AN interesting case of osteomalacia has been published by Dr. Holländer in the *Deutsche Medicinische Wochenschrift.* The patient was a woman, 36 years of age, who had for 10 years been suffering from what was supposed to be a rheumatic affection in the extremities and the chest, and finally she had become unable to walk. She said that during the last six or seven years her height had decreased by about 20 centimetres (eight inches) and on examination it was found that her lower ribs were in fact very near the iliac spines and that her vertebral column had sunk downwards and forwards. This had the effect of causing her arms to appear lengthened, her fingers reaching nearly to her knees. She walked in a very characteristic way: she fixed her knee-joints and by turning her body alternately to the left and to the right side she moved each leg slowly forward. At last she was not able to move even her legs but standing on her heels she made movements of rotation round her longitudinal axis. The suspicion that the case was one of osteomalacia was confirmed by means of the Roentgen rays, the radiograms showing that the rays passed easily through the decalcified bones. Internal treatment and orthopædic measures proved useless and Dr. Holländer then tried removal of the ovaries, a method employed successfully in two instances by Professor Hofmeier of Würzburg and Dr. Truzzi of Milan. The result was that on the third day the patient declared that she was able to breathe more freely than before and that she felt less impeded in her movements. In a fortnight she made her first attempt to walk and a month later she no longer required to use a walking-stick. At the present time, six months after operation, she is able to walk several kilometres (a kilometre is about five-eighths of an English mile)

The First-Aid and Accident Service.

Delegates from the larger towns representing the medical profession and the Government met recently in Berlin at the offices of the Government Medical Department which is attached to the Cultus-Ministerium, the object being to discuss questions connected with the first-aid and accident service. There has not hitherto been any uniform system of working adopted in this important organisation, as the municipal authorities have done but little in the matter. In some towns the employers' associations under the law relative to workmen's insurance against accidents have organised an accident service without the coöperation and to the prejudice of the medical profession. In Berlin the medical profession, together with some rich philanthropists, have also founded a special society for this purpose, so that there are two associations for first-aid the adherents of which often take opposite sides both in newspaper correspondence and at public meetings. Similar difficulties exist in some other places and the Government therefore convened the above-mentioned meeting for the purpose of settling the principles on which the first-aid service should be conducted with due regard to the interests both of the public and of the medical profession. The meeting after a long discussion adopted the following general principles. First-aid associations shall not continue to attend injured persons after first-aid has been rendered. It shall be the duty of the local medical association to organise the first-aid service. As a rule, first-aid is to be rendered in the accident wards of the public hospitals; when special premises other than the hospitals exist for the giving of first-aid such premises must be used for that purpose exclusively and not for the subsequent treatment of patients or for other cases. First-aid shall be given not by specially appointed surgeons but by any member of the medical profession who is willing to undertake such work. A central committee to act under the general supervision of the Government was then formed and Professor von Bergman was elected chairman. The committee will control the organisation of the accident service according to the above principles.

The Sick Clubs.

The Prussian statistical office reports that there exist under the Workmen's Insurance Act 9916 sick clubs with 4,337,714 members, of whom 844,217 are females, so that 137 per 1000 of the population belong to these clubs. On an average each member has to pay 16 marks 91 pfennigs (16*s.* 8*d.*) per annum, and the average expenses for each member are 15 marks 99 pfennigs (15*s.* 7*d.*), of which 98 pfennigs are for general expenses, 6 marks 46 pfennigs for maintenance during illness, 3 marks 24 pfennigs for medical aid, 2 marks 72 pfennigs for medicine, 1 mark 78 pfennigs for hospital expenses, and 80 pfennigs for other expenses.

Treatment of Foot-and-Mouth Disease in Cattle.

Professor Guido Baccelli of Rome, the well-known physician and at the present time the Italian Minister of Agriculture, not long ago recommended intravenous injections of corrosive sublimate as a certain cure for foot-and-mouth disease in cattle. The announcement attracted much attention and aroused great expectations, for this disease not only inflicts serious losses on agriculturists but it is sometimes communicated to the human subject. Professor Löffler of Greifswald and Dr. Uhlenhuth were therefore directed by the Prussian Government to make a fresh series of experiments on the effects of the treatment and their report is now published in the *Deutsche Medicinische Wochenschrift*, but it is unfortunately not at all favourable. In their experience injections of corrosive sublimate were useless as a prophylactic. Small doses of the drug neither shortened the fever nor reduced the local symptoms; when the dose was increased the symptoms were aggravated and the animals became emaciated. It could not be determined whether or not the injections diminished the mortality, for in Germany the disease is seldom fatal, but the investigations showed that the effect of corrosive sublimate was neither prophylactic nor curative.

Treatment of Inoperable Angioma.

Dr. Honsell of the Tübingen surgical clinic, writing to the *Beiträge zur Klinischen Chirurgie*, states that subcutaneous injections of alcohol have been found beneficial in the treatment of inoperable angioma. He describes a case in which a large and progressive angioma occupied the left side of the neck, the parotid region, and the cheek. Daily injections of from one to three cubic centimetres of an alcoholic solution were made round the growth at a distance of one centimetre from it, the alcoholic strength of the solution being at first 50 per cent. and afterwards 70 per cent. and the area inclosed by the injections being gradually reduced. The injections produced infiltration and cicatrisation of the perivascular interstitial tissue, resulting in contraction and obliteration of the enlarged blood-vessels.

April 14th.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Blackmailing Physicians in Toronto.

A MAN who recently tried to work a scheme on two well-known physicians of Toronto, charging them with improper conduct towards his wife, was brought for trial in the police-court. After putting up a lame defence for a few days he finally pleaded guilty to the charge. The court has sentenced him to one year and 164 days' imprisonment.

Canadian Medical Association.

The next annual meeting of the above association will be held this year in Montreal on Sept. 16th, 17th, and 18th, under the presidency of Dr. Francis J. Shepherd of that city. Professor Osler will deliver the address in medicine and Dr. John Stewart of Halifax, Nova Scotia, the address in surgery. Arrangements are already well in hand for a very successful meeting. Dr. George Elliott of Toronto is the general secretary.

Death of a Prominent Nova Scotian Physician.

By the death from appendicitis after but three days' illness of Dr. W. S. Muir of Truro, Nova Scotia, Canada has lost one of her ablest and most respected general practitioners. Dr. Muir was particularly prominent in the work of medical societies. He was the secretary of the Nova Scotia Medical Society from 1887 to the time of his death; in 1901 he was president of the Maritime Medical Association; and he has frequently been in office in the Canadian Medical Association. In fact, for years Dr. Muir did much of the executive committee work at the annual meetings of the last-named organisation. He was 49 years of age and graduated from the Halifax Medical School and Dalhousie University in 1874. He also took the L.R.C.P. & S. Edin. in 1877.

McGill University.

Two years ago the corporation of McGill University established a six-years' course for students in arts who desired to continue on in the study of medicine, certain of the primary medical studies being taken up by the arts students in the third and fourth years. Lately, the corporation has extended these privileges to students in the faculty of applied science. By this new arrangement students in that faculty may, if they so elect, obtain the degree of B.Sc. after four years and then continue on and secure the degree of M.D., C.M. at the end of the sixth year. In their third year they will attend lectures, in addition to the regular studies, in anatomy, physics, and histology; in the fourth year in anatomy, physiology, histology, pharmacology, and medical chemistry, and the two last years will be devoted to medical studies alone. The university has lately appointed a representative in London, England, Mr J Stuart Horner, and it is understood that an entrance examination in the faculty of applied science will be held in the metropolis on June 6th next.

Dr Roddick's Bill for a Dominion Medical Council

The Special Parliamentary Committee appointed by the House of Commons has reported favourably upon the passage of this measure, and if the Premier, Sir Wilfrid Laurier, does not, as intimated at the second reading of the Bill, oppose it any further, it will soon become an accomplished fact. In connexion with the refusal of the British medical authorities to recognise the diplomas and degrees held by Canadian surgeons now in South Africa, Dr J A. Kennedy of Nkandhla writes to a Montreal lay paper protesting against the non acceptance of these degrees in that country The letter is opportune and is of especial interest at the present time to Canadian university graduates, as Dr Roddick's Bill will seek to remedy this state of affairs. It certainly seems anomalous that while Canadians are accepted for service in South Africa their surgeons cannot attend to other than Canadian soldiers.

A Six Years Arts and Medical Course at Toronto University

Recently the Senate of Toronto University passed a statute by the terms of which it will be possible for any student, if he so desire, to secure the degree of B.A. at the end of the fourth year and then to proceed with the study of medicine and to secure the degree of M B at the end of the sixth year Anatomy and physiology with histology will be introduced into the arts course in the third and fourth years and medical studies proper will constitute the full curriculum in the fifth and six years It is a good sign when the two leading universities thus raise the standard in medical education

Immigrants Menacing the Health of Montreal

In September last the United States Immigration Department at Washington commissioned a court of special inquiry for the purpose of a medical inspection of immigrants arriving at Montreal and other Canadian ports of entry who were destined for points in the United States. The chief immigration inspector has recently made the statement that fully 98 per cent. of these immigrants are the subjects of favus and trachoma and, therefore, being undesirable immigrants they have been refused admission into the neighbouring Republic At the rate of from 40 to 50 per week they have been dumped into the city of Montreal since September last, and now Montreal is becoming alarmed and the attention of the Dominion authorities is being called to the matter and it is altogether likely that the Government will be compelled to take similar steps to those adopted by the United States Department of Immigration in order to protect the Canadian community from the introduction and spread of these two diseases the products of dirt and filth

Waste of Food in the United States

PROFESSOR W O ATWATER, who has gained a considerable amount of fame, not to say notoriety, in the United States on account of his views as to the effects of alcohol on the human system and who is an acknowledged authority on the question of nutrition has recently published for the United States Department of Agriculture a bulletin on the subject. Writing on the waste of food he says "The use of excessive quantities of food which is a common dietary error in this country among not only the well to-do but also those in moderate circumstances entails a waste of food in three ways" After explaining the three ways in which food is wasted he goes on to say 'Just where and among what classes of people the waste of food is greatest it is not possible to say, but there is certainly a great deal more of it in this country than in Europe. The worst sufferers from it are doubtless the poor but the large body of people of moderate means the intelligent and fairly well to-do wage-earners, are guilty of errors in this regard The common remark that 'the average American family wastes as much food as a French family would live upon' is greatly exaggerated, but statistics show that there is considerable truth in it. In dietary studies conducted in a students' club in an eastern college it was found that 10 to 14 per cent. of the nutritive materials purchased were thrown away as kitchen or table waste and yet the club members were trying to live as economically as was consistent with comfort. In private families the waste has been found to range from practically none to as high as 8 or 10 per cent , while in boarding houses, even where economy was sought, it has reached 10 and in individual instances 20, per cent , and in some public institutions where large numbers were fed it has been as high as 25 per cent. and even higher " England has always been regarded as a country in which waste of food was excessive. There can be no doubt, however, that the Americans are greater sinners in this respect, probably on account of the greater wage-earning capacity of the workers and the ignorance of the majority of the foreign immigrants In both countries the waste occurs principally among the lower, middle and working classes. A pamphlet dealing with the matter and embodying the facts published by Professor Atwater should prove an educating influence with these people and might be as useful in England as in America.

The Pennsylvania Society for the Prevention of Tuberculosis

This society has just completed its tenth year of existence and was the first of the kind to be organised in the United States—in fact, only one other society with the same object in view had been founded previously to the American "La Ligue contre la Tuberculose en France,' which was initiated in Bordeaux in 1896 The Pennsylvania Society has had a useful and successful career and has been able to exert a strong influence not only in the city and State in which it had it origin, but by its example and by means of its publications it has led to the establishment of similar societies elsewhere in the United States Perhaps the most valuable work done by the society has been the publication of a series of tracts for gratuitous distribution bearing on tuberculosis generally and especially intended to educate the community at large as to the most effective measures to be taken to avoid the contraction of consumption and to prevent its spread. 30 000 of these tracts were reprinted in 1891, in addition to the publication of a new one. The society in the spring of 1901 renewed its efforts to cause tuberculosis to be included among the diseases returnable to the Bureau of Health The subject was brought before the Philadelphia County Medical Society and was unanimously endorsed. The Bureau of Health was convinced by the solicitor of the society that it had the power to enforce registration of tuberculosis without a special Act of Legislature, and decided to include tuberculosis in the list of returnable diseases This action was approved by the Director of Public Safety but was disapproved by the mayor and consequently fell through. A similar fate met the efforts of the society to abate the spitting nuisance in public places.

Should a Physician be a Cultured Man?

The question as to whether a medical man needs polish and culture has on several occasions been made the subject of animated and at times somewhat acidulated discussion in the United States. Recently the matter has been brought up again and made the text for an article in the March number of the *Columbia Literary Monthly*, the principal undergraduate paper of the New York Columbia University The editorial article referred to takes the stand that only students having the Bachelor of Arts degree should be permitted to enter the Columbia College of Physicians and Surgeons on the ground that such a step would exclude the uncultured and uncouth. Harvard and Johns Hopkins make the possession of a degree in arts a *sine quâ non* of proceeding to the study of medicine. The article in the *Columbia Literary Monthly* ends as follows "Leaving aside, however the question of fitness to do work and turning to the wider sphere of the physician's effort it must be admitted, to state the case mildly, that culture and refinement are desirable in a doctor and it must further be admitted that the greater part of the students at our medical school are not only uncultured but often even uncouth thus being fundamentally unfit to become the highest type of their profession. A degree as the entrance requirement would go far to remedy this state Unfortunately, many worthy men would thus be barred out, but the good resulting from such an injustice would far outweigh the injustice itself and the benefit to the institution would be very great, although its number of students might be thereby diminished." It is said that the opinions so outspokenly expressed in the foregoing paragraph are shared by some of the University authorities and that they have recently considered the advisability of making the possession of the Bachelor of Arts degree an essential requirement for entrance to the University Medical School.

April 7th.

Obituary.

ALEXANDER MACGREGOR, M.D. ABERD., M.R.C.P. LOND.

WE regret to have to record the sudden death of Dr. Alexander Macgregor, which took place on April 12th at his residence, Queen-street, Berkeley-square. Dr. Macgregor was born in Invergordon 48 years ago, and was educated at a private academy and at Aberdeen University where he graduated as M.B., C.M. with highest honours in 1878. After a short period of study at Vienna and Berlin Dr. Macgregor returned to Aberdeen and started in practice, being at the same time demonstrator of anatomy to the late Sir John Struthers, then Professor of Anatomy in Aberdeen University. Later he became assistant to the Professor of Medical Jurisprudence and was also appointed to the medical staff of the Aberdeen Hospital for Sick Children and physician to the Aberdeen Dispensary. Then he was appointed assistant to the Professor of Medicine in the university and by the year 1895—the year when he decided to commence practice in London—he enjoyed one of the largest private practices in Aberdeen, his opinion being much sought in the north-east of Scotland. We have a special reason to regret Dr. Macgregor's early death, inasmuch as he was for many years our Special Correspondent in Aberdeen and on several occasions when a minute knowledge of Scottish affairs was required for the proper understanding of some educational or social problem we always found in him a wise counsellor. For Dr. Macgregor did not confine his interests to medical work but was well posted in all affairs connected with the development and student life of Aberdeen University; for example, he was one of the promoters of the Volunteer Medical Staff Corps of which he was a captain for a long period. When seven years ago he retired from his Aberdeen practice he took the Membership of the Royal College of Physicians of London and was elected physician to the North-West London Hospital for Diseases of the Chest. An able, kind, and genial man, his sudden death from angina pectoris while in the prime of life has caused a shock to a large circle of friends and patients. He is survived by a widow, with whom sympathy will be particularly felt as their child, a daughter, is only a few weeks old.

Medical News.

UNIVERSITY OF ABERDEEN.—The following degrees and diploma have been conferred:—

Honorary Degree of Doctor of Laws (LL.D.).—Sir Thomas Barlow, Bart., K.C.V.O., M.D., physician to His Majesty's Household

Degree of Doctor of Science (D.Sc.).—James Moir, M.A., B.Sc., Aberdeen.

Degree of Bachelor of Science (B.Sc.).—Peter Fraser, Lentran, Inverness; Henry William Malcolm, Aberdeen; and William Henry Wishart, M.A., Aberdeen.

Degree of Doctor of Medicine (M.D.).—Archibald Campbell Barron, M.B., C.M., Dailly, Ayrshire; †Robert Sinclair Black, M.A., M.B., C.M., Robben Island, Cape of Good Hope; †Henry Fraser, M.B., Ch.B., Aberdeen (under the New Regulations); *Frederick Theobald Keyt, M.B., C.M., British Honduras; Alexander Gordon Milne, M.B., C.M., Rodley, near Leeds; John William Myers, M.B., C.M., Shipley; James Farquhar Philip, M.B., C.M., West Ealing, London.

* Thesis considered worthy of "Honours."

† Thesis considered worthy of "Commendation."

Degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.).—*With First-class Honours*: Lewis Davie Cruickshank, Tarves, Aberdeenshire. *With Second-class Honours*: Robert Donald Keith, M.A., Kinnermit, Turriff, and Alexander Christie Reid, M.A., Ellon. *Ordinary Degrees*: Louis Coetzee, Kafferskraal, Steynsburg, Cape Colony; James Bremner Elder, Keith, Banffshire; Harry Willmott Elwell, Combe St. Nicholas, Chard, Somerset; George Bruce Killoh, Ardmurdo, Inverurie; Jeannie Charlotte Macleod, Aberdeen; Archibald Mahomed, London; James Burnett Rae, Aberdeen; Alexander Robertson, Elgin; Robert Boyd Robson, Edinburgh; John Stuart Rose, Culfoichmore, Grantown-on-Spey; Thomas Stewart Slessor, M.A., Aberdeen; James Souter, M.A., Aberdeen; and Alexander Watt, Ardwell, Cabrach, Aberdeenshire.

Diploma in Public Health.—William Fraser Bisset, M.B., Ch.B. (Aberd.), Aberdeen; Frederick Theobald Keyt, M.B., C.M. (Aberd.), British Honduras; and Ernest Hunt Nash, M.B., Ch.B. (Aberd.), Stafford (with credit).

UNIVERSITY OF BIRMINGHAM.—At the recent second examination for the degree of M.B., Ch.B., the following candidates were successful:—

Fred Thomas Hollway Davies, Fred Newton Walsh, and Herbert Henry Warren.

THE *Journal of Gas Lighting, Water-supply, and Sanitary Improvement* of April 8th says: "Among the forthcoming 'events' announced by the Crystal Palace Company is a Lighting, Heating, and Smoke Abatement Exhibition. The date fixed for the opening is Dec. 13th."

CENTRAL LONDON SICK ASYLUM DISTRICT.—The managers of the Central Sick Asylums, Cleveland-street and Hendon, at their meeting on April 7th decided to establish a department for the x-ray treatment of lupus. With the permission of the Local Government Board 25 cases can be sent to Hendon at a certain charge.

NEW PUBLIC BATHS AT FULHAM.—On April 10th the public baths and washhouses which have been erected at Walham-green by the Fulham Borough Council at a cost of over £62,000 were declared open by Mr. John McDougall. The building contains three swimming-baths, 84 private baths, and washhouse stalls for 66 washers.

PRESENTATIONS TO MEDICAL PRACTITIONERS.—The members of the ladies' class of the Exmouth branch of the St. John Ambulance Association on April 5th presented Mr. J. Willoughby Hodgson, M.D., C.M. Aberd., M.R.C.S. Eng., with a revolving chair in appreciation of his services as honorary lecturer.—On April 8th the members of the ladies' class of the St. John Ambulance Association at St. Colomb, Cornwall, presented Mr. J. C. Mackay, M.D. St. And., L.R.C.P. & S. Edin., with a gold-mounted umbrella, engraved with a suitable inscription, and a fountain pen, as a mark of appreciation for his services as honorary instructor.—Mr. Duncan MacDonald, M.B., M.S. Glasg., late medical officer of Torosay, Mull, at a recent meeting at Salen received a purse of 102 sovereigns and an illuminated address in token of high esteem and as an expression of goodwill on the occasion of his leaving the district.

THE ROYAL INSTITUTION.—Problems of the Atmosphere formed the subject of the Friday evening discourse delivered at the Royal Institution by Professor James Dewar on April 11th. In reference to the question of atmospheric hydrogen, which was discussed at some length, he said that the atmosphere probably contained free hydrogen emitted from volcanoes or disengaged from water by the action of metals, but the proportion of it could hardly exceed 1 part in 40,000 or 50,000. Gautier, however, had found one part of hydrogen in 5000 parts of air, the true explanation of which probably was that as he used a long metallic tube for bringing air from outside into his laboratory metallic particles from this tube were carried into the chemicals used for drying the air. In his experiments Professor Dewar had used a liquefying apparatus which liquefied all the recognised atmospheric gases except helion. It was also not it capable of liquefying hydrogen and in this way it served to detect minute known quantities of hydrogen purposely added to the air under examination. The incondensable residue separated by this apparatus never exceeded 1 part in 35,000 or 40,000 parts of normal air. For the study of the constitution of the atmosphere it would be very helpful if samples of air could be taken at a height of about 20 miles, for theoretical considerations pointed to important differences in the proportions of its constituents at great elevations—namely, that there would be no carbonic acid above 18 miles, no oxygen above 37 miles, and no nitrogen above 62 miles. With regard to the inter-planetary space, one school held that it had no temperature (i.e., that it was at − 273°C.) and consequently contained no gas, while another school held that it had a temperature of – 140°C In conclusion the experiment of the distillation of ice at a very low temperature was shown.

BOLINGBROKE HOSPITAL.—The report of this institution for the year 1901 states that the amount of the annual subscriptions is smaller than that received in 1900 and, although the donations are larger, increased subscriptions are greatly needed. Through the opening of the new out-patient department, which is now fully equipped, a great boon has been given to the patients who attend for treatment. The cost of the new building was £5545 and of this amount the sum of £4200 has been paid, leaving a debt of £1345 Towards the debt the governors have in hand £728. This institution offers to such persons as are able to pay, wholly or partially, the advantages of hospital treatment and nursing with, as far as possible, the comfort and privacy of a home. Patients may be attended by their own medical advisers Out patients are referred to medical practitioners in the neighbourhood before hospital treatment is given. The report contains an address reprinted from THE LANCET of Dec 14th, 1901, p 1654, on a Model Hospital, which was delivered at the opening of the new Victoria wing for out patients on Dec. 11th, 1901, by Mr Thomas Bryant.

DONATIONS AND BEQUESTS TO HOSPITALS—Mrs Disney Thorp of Cheltenham has bequeathed £5000 to Cheltenham General Hospital and £1000 to the Leeds Infirmary —Mr Frederick Sigismund Schwann of Wimbledon has by his will bequeathed £100 to University College Hospital.—Mr Frederick Flood of Denfield, Dorking, has by his will bequeathed £3000 on deposit with Messrs. Thomas Wood and Co., of the Old Bank, Dorking, in trust for the Dorking Cottage Hospital and other charities.—By the will of Mrs Sarah Leetham, of South Kensington, the sum of £100 is left to the East Sussex Hospital Hastings, and to the Hospital for Sick Children, Hull.—The Royal Free Hospital has received a donation of £100 from the Clothworkers' Company, which has also voted a donation of £50 to the City Orthopædic Hospital.—Lord Eldon has given £50 and Mrs. Elizabeth Campbell £50 to the funds of the City Orthopædic Hospital.—Under the will of Miss Margaret Ann Lachlan of Kensington gardens the Royal Home for Incurables, Streatham, receives £500, the Surgical Aid Society £200, and the Royal London Ophthalmic Hospital £100

CHILDHOOD SOCIETY—At the annual meeting of the Childhood Society for the Scientific Study of the Mental and Physical Condition of Children, held on March 19th, Earl Egerton of Tatton was re-elected president and Mr R. B Martin, M.P, was re-elected treasurer The council's report for 1901 gives the full text of a memorial submitted by the president to the Duke of Devonshire, President of the Committee of the Privy Council on Education This memorial embodies several 'conclusions," of which the principal are as follows (1) of the school-children observed about 1 per cent. are either physically or mentally deficient to a marked extent, (2) special separate classes for such defective children should be formed in the area of every educational authority in the interest of the children themselves, of others, and of the country at large, (3) instruction in the peculiarities of, and special training for, such children should be given to all the teachers, and (4) the method of education should be such as would lead to the elimination of a tendency to mental defects, especially those of a nervous origin, as otherwise the school life may tend rather to the accentuation of such defects. The memorial goes on to recommend (1) that a scientific commission of inquiry should be appointed by the Government for the purpose of determining the conditions of portions of the school population as to their mental and their physical power and of ascertaining the numbers of such as are of imperfect development together with the possible causes of such defects, (2) that the Act of 1899 Elementary Education (Defective and Epileptic Children) should be made compulsory, and (3) that scientific experts should be appointed to assist the Board of Education with regard to the means to be adopted for the education of children requiring special care. The first volume of the Transactions of the society is being issued this year, it contains a portrait and memoir of the late Sir Douglas Galton together with a variety of papers on subjects connected with the work of the society It may be obtained at the Parkes Museum, Margaret street, London, W

Parliamentary Intelligence.

HOUSE OF COMMONS

THURSDAY, APRIL 10TH

The Small-pox Hospital Ships in the Thames

Colonel TUFNELL asked the President of the Local Government Board if his attention had been drawn to the resolution unanimously passed by the Essex County Council against the use of the hospital ships for small pox cases and urging (if they must be retained) that they should be used only for convalescent cases, and what steps he proposed to take in the matter —Mr GRANT LAWSON on behalf of Mr LONG replied: I understand that the Essex County Council has passed a resolution on this subject. The number of small pox cases under treatment is still very large, and as I stated in reply to a question by my hon and gallant friend in January last, I do not propose to interfere with the discretion of the managers of the Metropolitan Asylums District as to the use of the hospital ships. The managers are endeavouring to provide adequate hospital accommodation on the land but I cannot at present say that it will be found practicable to restrict the use of the ships to convalescent cases only

FRIDAY, APRIL 11TH.

Medical Examination of Yeomanry Recruits

Sir ELLIOTT LEES asked the Secretary of State for War whether his attention had been directed to a new attestation form (Army Form E. 695) for yeomanry recruits issued to home yeomanry regiments in which a certificate of medical examination was required in the form set out; whether the only persons allowed by the War Office medically to examine recruits for the home yeomanry were all medical officers and civil practitioners authorised to examine recruits and medical officers of regiments of Imperial Yeomanry in Great Britain; whether it had been brought to his notice that in agricultural counties this regulation either entailed on recruits living remote from an authorised medical examiner loss of time and expense in travelling or similar loss to medical officers of yeomanry regiments who were civil practitioners and whether with the view of preventing detriment to recruiting he would sanction the medical examination of recruits for the Imperial Yeomanry in Great Britain by any resident civil practitioner at places where an officer qualified under the regulation mentioned was not available or would he consider the advisability of compensating the recruits and yeomanry medical officers for their losses and expenses.—Lord STANLEY, for Mr BRODRICK replied: It rests with the general officer commanding and the principal medical officer in each command to make the necessary arrangements for the examination of yeomanry recruits To meet the special circumstances of the yeomanry extra civil medical practitioners can be appointed when necessary the expenses being recovered under the conditions of paragraph 483 of the Militia Regulations

MONDAY, APRIL 14TH.

Typhoid Inoculation Among the Troops

Captain NORTON asked the Secretary of State for War if he could state whether the report on the results of anti typhoid inoculation had been received, and if so would he say whether it showed a diminution in mortality in inoculated persons attacked by the disease as compared with those uninoculated, whether it showed a diminished evidence of the disease in inoculated persons and whether the full report would now be laid upon the table.—Lord STANLEY for Mr BRODRICK, replied: The report has been received It deals with only 4138 cases and the aggregate results show a mortality of 8·2 per cent. in inoculated persons as against 15·1 per cent. in uninoculated persons The report however does not appear sufficiently conclusive in itself and it seems expedient to obtain further statistics from the admission and discharge books before publishing it.

Medical Certificates for the Post Office Service.

Mr JAMES O'CONNOR asked the Secretary to the Treasury, as representing the Postmaster-General if he would explain why suboffice rural postmen who were not allowed free medical attendance were compelled to furnish the department with a weekly medical certificate when they were on the sick list at their own cost and whether the department would dispense with weekly certificates in cases where the men's illness was known to be of several weeks duration; also whether the department would see its way to refund to the men the cost of these certificates.—Mr AUSTEN CHAMBERLAIN replied: All servants of the department are required to furnish weekly certificates when absent through illness and at places where there is no medical officer attached to the Post Office the certificate must be obtained from the patient's own medical adviser The Postmaster-General is not prepared to alter the rule which requires medical certificates to be furnished nor can he undertake to refund the cost of them to those officers who are obliged to obtain them at their own expense.

Deaths from Plague in the Punjab

Mr CAINE asked the Secretary of State for India whether he could state how many deaths from plague had occurred daily in the Punjab; and whether the recommendations of the Plague Commission with regard to securing the coöperation of the people in administering plague measures which were followed in the Bombay Presidency were being adopted in the Punjab.—Lord GEORGE HAMILTON replied: I receive no daily returns of plague deaths. The telegraphic reports are for periods of four weeks and these are subsequently supplemented by certain weekly returns and details The number of deaths from plague in the Punjab since the autumn of 1901 have I regret to say greatly increased and are as follows—viz.: for the four weeks ending Jan 18th 1902 9438; for the four weeks ending Feb 15th 1902, 16 784; and for the four weeks ending March 15th, 1902, 42,788. No later reports have yet been received Regulations enjoining measures based on the recommendations of the Plague Commission and designed to avoid coercion and to attract the cooperation of the people as much as possible have been adopted and a specially qualified medical officer has been deputed to supervise the preventive arrangements

The Budget.

The CHANCELLOR of the EXCHEQUER presented his annual Budget at this sitting. On the basis of existing taxation it showed a deficit of £45,500,000. To meet this deficit the Chancellor of the Exchequer proposed to suspend the sinking fund, thus accounting for £4,500,000; to add one penny to the income tax, estimated to produce £2,000,000; to increase the stamp for cheques and dividend warrants from one penny to twopence, estimated to produce £500,000; to revive the old registration duty on all imported corn and grain and flour and meal, estimated to produce £2,650,000; to borrow by special loan £32,000,000; and to draw on exchequer balances to the extent of £3,500,000. The registration duty was repealed by Mr. Lowe in 1869. The proposal now is to revive it in the form of an impost of threepence per cwt. on corn and grain, and fivepence per cwt. on flour and meal. According to the statement of the Chancellor of the Exchequer this tax will represent a small fraction of a farthing on each two-pound loaf.

TUESDAY, APRIL 15TH.

The Sale of Patent Medicines.

Mr. LAYLAND-BARRATT asked the Chancellor of the Exchequer whether, in cases where penalties under 42 George 3, c. 59, for selling medicines without affixing the stamps in payment of duty required under that Act were not recovered by process of law, but were claimed by, and paid direct to, the Inland Revenue authorities, the informer was entitled to any portion of such penalties; and, if so, to what portion; and whether, if the informer was a Government official, he was entitled to a similar or any portion of the penalties.—The CHANCELLOR of the EXCHEQUER replied: The Board of Inland Revenue is empowered to grant rewards to informers, whether Government officials or otherwise, in cases of the kind referred to. The amount awarded depends upon the circumstances of each individual case.

The Ventilation of the House.

The following Members were nominated as a Select Committee t inquire into the ventilation of the House—viz., Mr. Akers-Douglas, Mr. John Dillon, Dr. Farquharson, Sir Michael Foster, Mr. Goddard, Mr. John Penn, and Sir John Batty Tuke.

Cremation Bill.

This Bill, which has passed through all its stages in the House of Lords, was read a second time and on the motion of Sir WALTER FOSTER was referred to the Grand Committee on Law.

ROYAL COMMISSION ON ARSENICAL POISONING.

THE Royal Commission on Arsenical Poisoning held a meeting for the examination of witnesses on April 11th in the Westminster Palace Hotel, Victoria-street, S.W. The Commissioners present were Lord Kelvin (chairman), who presided, Sir William Church, Sir William Hart-Dyke, M.P., Professor Thorpe, and Dr. B. A. Whitelegge, with Dr. G. S. Buchanan (secretary to the Commission). Four witnesses were examined, all of them from Halifax, and their evidence had reference, more or less direct, to the recent outbreak of arsenical poisoning in that town.

Mr. G. S. THOMSON representing Whittaker's Brewery, Halifax, was the first witness and in the course of his examination he took exception to certain statements made in the report with reference to the outbreak by Mr Hammond Smith, assistant commissioner. He denied that a particular patient had been a regular customer at a certain inn owned by the brewery; the man had only called at the inn a few times. He also disputed the accuracy of a statement with regard to the source of certain invert sugar. Witness explained to the Commission the system of malting adopted by the brewery. Their kiln, he said, had three floors for the accommodation of grain and below the first of these floors was a hot chamber into which, in the first instance the fumes of the fuel entered. When the malt was finished—that was to say, after it had been on the bottom floor—it was screened and brushed as a precaution against the presence of arsenic It was tested periodically for arsenic and once or twice before it had been screened and brushed slight traces had been found. The hot chamber, or "dust chamber," as it was usually called, was cleared out twice a year. The dust collected had been analysed and traces of arsenic had been found in it. Since the Halifax scare they had been using better fuel for malting—oven coke and anthracite coal Prior to the Manchester scare they did not have the beer analysed, but subsequently to that time and prior to the Halifax scare they had samples analysed practically every week. The reports which they received had always been good. In one or two cases there had been found faint traces of arsenic in the malt and in the beer but not in the materials. Since the Halifax scare they had had the beer analysed by more than one analyst. The analyses varied a great deal; in fact, there were scarcely two which agreed. They had a sample of finished beer analysed by three analysts who brought out three distinct results. Brewers were very much dissatisfied with this state of things and, indeed, their faith in analysis had been greatly shaken. They would like to see one standard or method of analysis applied in every case. Up to January, 1902, about 85 per cent. of the fuel they used was Halifax gas coke. The anthracite coal which they now used had been analysed and had showed no trace of arsenic. After brushing and screening the malt it had been found free from contamination. No doubt arsenic might be carried up the flue for it had been found adhering to the girders at the top. They wished to keep in line with other brewers and would not think of reverting to gas coke and in the light of present information it would be wrong to omit brushing and screening of the malt.

Dr. J. T. NEECH, medical officer of health of the Borough of Halifax, gave the Commission an account of 13 cases of arsenical poisoning which had come to his knowledge, all of which he attributed to the presence of arsenic in beer. In his opinion, one-fiftieth of a grain per gallon would be dangerous and as a matter of fact he did not think that more than one-hundredth of a grain ought to be allowed In the case of persons who were susceptible to poisoning by arsenic anything between one-fiftieth and one-hundredth of a grain per gallon would affect health materially. He was not an analytical chemist but he had one or two ideas about the varying results of analyses of the same beer. For instance, yeast took up a considerable amount of arsenic and if a sample were taken from near the bottom of a cask there might be more yeast cells in it than in the beer at the top of the cask and consequently there would be more risk of arsenic. Another point was that analysts had been using different tests. Speaking as a medical man he had no doubt that the symptoms in these Halifax cases were the symptoms of arsenical poisoning and his view was that greater care should be taken in regard to the fuel used in the preparation of the malt. During the period of the Manchester scare he saw one or two cases of arsenical poisoning in the workhouse and he also heard that there were one or two cases in private practice but the doctors at that time refused to give him the names and consequently he was unable to see the cases. Prior to the Manchester scare he had no reason to believe that there were cases of arsenical poisoning in Halifax. At the brewery of the Messrs. Webster in Halifax he had had an experimental kiln erected. In the first experiment ordinary gas coke was used and the malt was placed upon the kiln in a very wet condition. The unbrushed malt was found to contain $\frac{1}{11}$th of a grain of arsenic per pound and the brushed malt $\frac{1}{12}$th of a grain per pound. In the second experiment the malt was hand dried and put on the kiln practically dry, and as in the first experiment ordinary gas coke was used. The unbrushed malt was found to contain $\frac{1}{60}$th of a grain of arsenic per pound and the brushed malt $\frac{1}{30}$th of a grain per pound. The next two experiments were made with gas coke which had been arsenicated. With wet malt unbrushed the analysis gave one-ninth of a grain of arsenic per pound, and with the same malt brushed one-eighth of a grain per pound. With dry malt unbrushed it gave $\frac{1}{17}$th of a grain per pound and with the same malt brushed it gave $\frac{1}{11}$th of a grain per pound. The fumes of the coke passed from an empty chamber direct to the malt. In the cases of the brushed malt of No. 2 experiment and of the brushed malt of No. 4 experiment he removed the husk of a small quantity of each malt and submitted it for analysis. In the one case the husk gave $\frac{1}{60}$th of a grain of arsenic per pound, and in the other $\frac{1}{10}$th of a grain, these figures showing that the arsenic was chiefly deposited on the husk. He had expected the wet malt to take up more arsenic than the dry but in the first two experiments made with ordinary coke the dry malt took up rather more arsenic than the wet, but of course there might be more arsenic in one lot of coke than in another though both were taken from the same bulk. In the second pair of experiments he thought the coke was practically the same and the dry malt took up only one-half the amount of arsenic taken up by the wet. The wet malt when brushed seemed to show more arsenic than when unbrushed but the dry malt rather less. Analyses were taken of the tongues in the third and fourth experiments and gave $\frac{7}{10}$ths of a grain per pound and $\frac{1}{4}$th of a grain per pound respectively. In the one case the malt was very wet when put on the kiln and in the other it was dry.

By Professor THORPE No steps were taken to see whether the barley was free from arsenic but the same barley was used in all the experiments.

By Sir WILLIAM CHURCH: The experiments were few in number and he did not want to dogmatise upon them, but they seemed to indicate that brushing was not so great a safeguard as some brewers imagined.

By Dr. WHITELEGGE: Prior to the Manchester scare he had never taken samples of beer for analysis, but in the light of what had occurred since then he thought they should be taken as a matter of routine. As soon as he became aware of the cases in Halifax, he caused samples of beer to be taken for analysis. The first lot of six samples were submitted to the public analyst of Halifax who reported them to be absolutely free from arsenic. Other samples were submitted to Mr. Richardson of Bradford who reported the presence of arsenic in them. He doubted whether he had power under the Sale of Food and Drugs Act to enter a brewery and to take samples of the malt, but no question of this kind had arisen as he had received every facility from the local brewers.

Mr. F. BUCKLEY, managing director of Messrs. Webster's brewery, Halifax, said that since November, 1901, they had had all their materials analysed before being used in the brewery and all the beers before being sent out to customers. He assured the Commission that the brewers of Halifax had done everything in their power to prevent contamination. In the case of his own firm they had put up a new kiln with all the latest improvements. Brewers would like to see some standard of analysis set up because in the present state of things they found very considerable variations in the results reported. In one case the Inland Revenue authorities sent a sample of beer to Somerset House and it was reported to contain $\frac{1}{40}$th of a grain of arsenic per gallon and when a sample of the identical beer was sent to Mr. Richardson of Bradford he reported it as containing $\frac{1}{140}$th of a grain. Some brewers were using lime as a protection against arsenic and he felt sure that all of them would be happy to fall in with any suggestion which might be made by the Commission. There could be no doubt that the great bulk of the beer sent out in the Halifax district in 1901 was made with malt in the preparation of which gas coke had been used. He considered screening and brushing to be a great safeguard and it was much resorted to now that the risk of arsenic was known. His firm used to employ gas coke, then they tried oven coke, and now they only used anthracite coal.

Mr. WORSICK, maltster, Alland, near Halifax, was the last witness examined. He said that when the Manchester scare occurred it was thought that all the danger arose from the use of glucose, but since then it had been discovered that the malt was liable to contain arsenic and greater care had been taken in the preparation of malt. In his own case he had improved his methods and machinery and for fuel used anthracite coal. There was now a general opinion in the trade that gas coke was unsuitable for malting.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

BJORNSON, O., M.D., C.M. Manitoba, has been appointed Clinical Assistant to the Chelsea Hospital for Women.

BRANDSON, B. J., M.D., C.M. Manitoba, has been appointed Clinical Assistant to the Chelsea Hospital for Women.

BUTLER, Hon. G. H., M.R.C.S., L.R.C.P. Lond., has been appointed Honorary Medical Officer to Hobart Hospital, Tasmania.

COLLINS, J. C., M.B. T.C.D., has been appointed Senior Medical Officer at the Auckland Hospital, New Zealand.

DASHWOOD, HOWARD A., B.A. Cantab., M.D. Brux., M.R.C.S., L.R.C.P. Lond., has been appointed Public Vaccinator for the Parish of Hampton Hill by the Kingston Board of Guardians.

DODS, JOSEPH E., M.B., B.S. Edin., has been appointed Acting Medical Officer, Brisbane, Queensland, in connexion with the Diamantina State Children during the absence on leave of Mr. K. I. O'Doherty, F.R.C.S. Irel.

DUNLOP, JAMES CRAUFURD, M.D. Edin., has been appointed Inspector of Certified Inebriate Reformatories in Scotland under the provisions of the Inebriates Acts, 1879 to 1900; and also Inspector of Retreats licensed under these Acts in Scotland.

HARVEY, FRANK, M.R.C.S., L.S.A., has been appointed Medical Officer of the Padstow (Cornwall) Port Sanitary Authority.

HORNE, MAYNARD, M.A., M.B., B.C. Cantab., M.R.C.S., L.R.C.P. Lond., has been appointed Assistant Anæsthetist to the National Orthopædic Hospital, Great Portland-street, W.

HUNTER, JESSIE S. B., M.B. Glasg., has been appointed Assistant Medical Officer to the Lawn Hospital for the Insane, Lincoln, vice Mr. K. D. Cooper, resigned.

JARDINE, ROBERT, M.D. Edin., M.R.C.S., F.F.P.S. Glasg., F.R.S.E., has been re-appointed Obstetric Physician to the Glasgow Maternity Hospital.

KELLY, T. W. G., M.D. T.C.D., has been re-appointed Medical Officer to the Market Bosworth Rural District Council.

LARWILL, JOHN, L.R.C.P. & S. Edin., has been appointed Medical Officer at Boonal, Queensland, vice Jas. H. Finemore, L.R.C.P. Edin.

LOGAN, R. R. W., M.R.C.S., L.S.A., has been appointed Certifying Surgeon under the Factory Acts for the Ashby-de-la-Zouch District of Leicestershire.

LOVE, WILTON WOOD RUSSELL, M.B. Edin., has been appointed Deputy Commissioner of Public Health for Queensland during the absence of the Commissioner of Public Health.

MATSON, J. A., B.A., M.D. Dub., L.R.C.P. Irel., has been appointed Assistant Physician to the Richmond, Whitworth, and Harwicke Hospital.

PURNELL, RICHARD, M.D. St. And., M.R.C.S., L.S.A., has been appointed Medical Officer of Health of Wells (Somerset) for three years.

SODHI, BABA M. SINGH, M.B., Ch.B. Edin., has been appointed Assistant Medical Officer at the Borough Asylum, Portsmouth.

STEVENSON, ROBERT, M.B., M.S. Glasg., has been appointed District Surgeon of Prince Albert, Cape Colony, South Africa.

TAYLOR, F. H., M.B., Ch.B. Vict., M.A., M.Sc., M.R.C.S., L.R.C.P. Lond., has been appointed Pathologist to the Chelsea Hospital for Women.

TUKE, G. M., M.R.C.S., has been re-appointed Medical Officer of Health to the Hollingbourne Rural District Council.

TURNER, H. R., M.B., M.S. Aberd., has been appointed Medical Officer and Vaccination Officer for Kinnellar.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BIGGLESWADE RURAL DISTRICT COUNCIL.—Medical Officer of Isolation Hospital and Small-pox Hospital. Salary £60 a year, additional fee of £5 5s. a week if and when patients are treated in the small-pox hospital.

BRENTFORD UNION WORKHOUSE AND SCHOOLS, Isleworth.—Assistant Medical Superintendent, unmarried. Salary £120 per annum, with apartments, rations, washing, &c.

BRIDGWATER INFIRMARY.—House Surgeon. Salary £80 a year, with board and residence.

BUCKINGHAMSHIRE ROYAL HOSPITAL, Aylesbury.—Resident Surgeon, unmarried. Salary £80, increasing to £100, with board and apartments.

CAMBRIDGESHIRE, ETC., LUNATIC ASYLUM, Fulbourn, near Cambridge.—Assistant Medical Officer (unmarried). Salary £150 per annum, with board, lodging, and attendance.

CANCER HOSPITAL, Fulham-road, S.W.—Junior House Surgeon. Salary at rate of £70 per annum, with board and residence.

CARMARTHENSHIRE INFIRMARY.—Resident Medical Officer, unmarried. Salary £100 per annum, all found.

CENTRAL LONDON SICK ASYLUMS at Cleveland-street or Hendon.—First Assistant Medical Officer. Salary £120 per annum, with board and residence.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Registrar. Honorarium of 20 guineas per annum.

CITY OF NOTTINGHAM PARISH INFIRMARY.—Assistant Medical Officer. Salary £100 per annum and rooms.

CORNWALL COUNTY ASYLUM, Bodmin.—Junior Assistant Medical Officer, unmarried. Salary £120, rising to £150, with board, apartments, &c.

CUMBERLAND AND WESTMORLAND ASYLUM, Garlands, Carlisle.—Junior Assistant Medical Officer, unmarried. Salary £130, rising to £150 per annum, with board, lodging, &c.

DUDLEY, THE GUEST HOSPITAL.—Assistant House Surgeon for six months. Salary £40 per annum, with residence, board, and washing.

DURBAN, NATAL, SOUTH AFRICA.—Medical Officer of Health. Salary at rate of £750 per annum.

DURHAM COUNTY ASYLUM.—Junior Assistant Medical Officer wanted. Salary £150, rising to £180 a year, with apartments, board, laundry, and attendance.

DURHAM COUNTY HOSPITAL.—House Surgeon. Also Assistant House Surgeon. Salary of Senior £120, of Junior £65, with board and lodging in each case.

FISHERTON ASYLUM.—Assistant Medical Officer, unmarried. Salary £150 per annum, with board, lodging, and washing.

GREENWICH UNION INFIRMARY.—Junior Assistant Medical Officer, unmarried. Salary £100 per annum, with board, lodging, washing, and attendance. Also Second Assistant Medical Officer, unmarried. Salary £100 per annum, with board, lodging, washing, and attendance.

HOSPITAL FOR DISEASES OF THE THROAT, Golden-square, W.—Senior Clinical Assistant.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Surgeon, unmarried, for six months. Salary £20, washing allowance £2 10s., with board and residence. Also Medical Registrar. Honorarium 50 guineas a year.

INDIAN MEDICAL SERVICE, India Office.—Not fewer than Twelve Commissions.

KENT AND CANTERBURY HOSPITAL.—Surgeon.

LEEDS GENERAL INFIRMARY.—House Physician for six months. Board, lodging, and washing provided.

LONDON TEMPERANCE HOSPITAL, N.W.—Assistant Resident Medical Officer for six months. Honorarium at rate of 50 guineas per annum, with board and residence.

MANCHESTER SOUTHERN AND MATERNITY HOSPITAL.—Resident House Surgeon. Honorarium £50 per annum and board.

MEDICAL DEPARTMENT OF THE NAVY, Admiralty, Northumberland-avenue, W.C.—Not less than Thirty Commissions as Surgeons.

METROPOLITAN ASYLUMS BOARD ASYLUM, Caterham, Surrey.—Assistant Medical Officer, unmarried. Salary £150 per annum, rising to £170, with rations, lodging, attendance, and washing.

PADDINGTON GREEN CHILDREN'S HOSPITAL, London, W.—House Physician, also House Surgeon, both for six months. Salary at rate of 50 guineas a year, with board and residence.

PORTSMOUTH ROYAL HOSPITAL.—Assistant House Surgeon. Salary £50 per annum, with board and residence.

ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—Casualty House Surgeon for six months. Board, &c., are provided.

ROYAL NATIONAL MISSION TO DEEP SEA FISHERMEN, 181, Queen Victoria-street, E.C.—Surgeon on Mission Hospital Vessel. Salary £4 a week.

STOCKPORT INFIRMARY.—Assistant House and Visiting Surgeon. Salary £80 per annum, with residence, board, and laundry.

TAUNTON AND SOMERSET HOSPITAL.—Assistant House Surgeon for six months. Salary at rate of £80 per annum, with board, lodging, and laundry.

TEIGNMOUTH HOSPITAL, S. Devon.—House Surgeon. Salary £70 a year, with board, lodging, and washing.

WALLASEY DISPENSARY AND VICTORIA CENTRAL HOSPITAL, Liscard.—House Surgeon, unmarried. Salary £100, with board and residence.

WESTERN GENERAL DISPENSARY, Marylebone-road, N.W.—Second House Surgeon, unmarried. Salary £80 a year, with board, residence, and laundry.

WESTMINSTER HOSPITAL, Broad Sanctuary, S.W.—Surgical Registrar. Salary £50 per annum.

WEST NORFOLK AND LYNN HOSPITAL, King's Lynn.—House Surgeon. Salary £100 per annum, with board, residence, and washing.

Births, Marriages, and Deaths.

BIRTHS.

SELLORS.—On April 7th, at 14 Emmanuel-road, Balham, the wife of T. B. Sellors, L.R.C.S., L.S.A., *of a son.*

SMELT.—On April 10th, at Holloway-road, Islington, N., the wife of C. A. Casterton Smelt, M.B., C.M. Edin., of a son.

THOMSON.—On April 14th, at 14, Coates-crescent, Edinburgh, the wife of John Thomson, M.D., F.R.C.P. Edin., of a daughter.

MARRIAGES.

DAY—COCHRANE.—At St. Peter's Church, Dublin, by the Rev. S. Robinson, M.A., Lieutenant-Colonel J. D. Day, late R.A.M.C., son of the late A. M. Day, Dublin, to Margaret Louisa, daughter of Sir Henry Cochrane, D.L., Woodbrook, co. Dublin.

HARDY—BALL.—On April 5th, at Isipingo, Natal, Leonard Ernest Hardy, M.B. Edin., to Sarah Elizabeth Ball.

DEATHS.

FELL.—On April 2nd, at Bibianaha, Ashantee, in his thirty-first year, William George Fell, M.B., B.S. Durham, eldest son of John Fell, 5, Eslington-road, Newcastle-on-Tyne.

MACGREGOR.—Suddenly, on April 12th, at 2, Queen-street, Berkeley-square, London, Alexander Macgregor, M.D. Aberd., M.R.C.P. Lond.

MAYO.—On April 7th, at Spittlegate House, Grantham, Eleanor, wife of A. C. Mayo, St. George's-park House, Great Yarmouth, aged 58 years.

WILLIAMS.—On April 10th, at Hill House, Clay Cross, in his thirty-ninth year, Evan James Williams, L.R.C.P., M.R.C.S., youngest son of the late James Williams, Esq., J.P., Cardigan.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

MEDICINE IN ANTIQUITY.

ONCE more we have to announce the discovery of a Roman oculist's seal, and again the relic hails from ancient Gaul, it having been found at Sanites. A description of it may be read in the *Revue des Etudes Grecques*, but as the summary there is very short and as that journal may not be easily available we give the text in full and a few words of explanation for those interested in such subjects. The inscription upon the signet reads, "Val Philerotis Italic. ad Diathes(is). Val Philerotis Cycnivm Lene." The owner's name, Valerius Philerotis is new, but the remedies which this record shows that he specially approved and had therefore engraved upon his seal are similar to those previously found upon such objects. What were the ingredients of italicum is a mystery. It has only once been read upon a seal and is untraceable in any extant classical medical author. The seal upon which it has previously been found was preserved at Contines and belonged to one Marcus Julius Sabinus, who used it "ad cicatrices," that is for disease of the pupils and transparent cornea. It may have been for the same complaint that Philerotis applied it, because "diathesis" really was merely a broad term for any morbid ailment, particularly, however, of the eyes, and is a word frequently used by Galen in this sense and once or twice by both Marcellus and Scribonius. It occurs about twenty times upon oculist's seals. "Cycnium," "Cycni"(on), "Cy"(cnarium), or "Cyknaria," has been deciphered upon five seals. Three of these omit the malady for which it was applied; the other two state that it was a cure "ad impetum," that is to say, incipient ophthalmia. Cycnium may mean simply white, the colour of a swan. Further information may be found in Galen, Paulus Aegineta, or Oribasius. One seal gives a collyrium "Cynon," which may be an error of the engraver for cycnion. The seal states that this cynon was applied "ad claritatem," which indicates its supposed effect. "Lene" simply means sweet or pleasant and does not present any addition to the Pharmacopœia. Aetius speaks of it several times.

DIFFICULTIES UNDER THE NOTIFICATION ACT.

ON April 3rd Mr. A. A. Rostant of Tottenham was summoned at the instance of the Edmonton Urban District Council for wilfully aiding and abetting a man named Wood in exposing himself while suffering from small-pox. The evidence showed the following facts. Mr. Rostant said that he first made up his mind that Wood was suffering from small-pox on Jan. 16th. He wrote out a notification and told Wood to drop it into the letter-box of the medical officer of health, Dr. C. H. Adamson. He could not remember whether he told Wood that he had small-pox. Wood said that he went to Dr. Adamson's surgery and sat down to wait. Dr. Adamson said that he found Wood sitting in the surgery and saw that he was suffering from small-pox. He wrote to Mr. Rostant. He called Wood out of the surgery and told him to go straight home. Wood further said that when he got home he remained there for a fortnight seeing no medical man. He was then removed to the hospital. The sanitary inspectors called. His wife and children were living in the house and the wife looked after him. Eventually the magistrates, though agreeing that it was quite right to bring the case into court, did not convict. Mr. Rostant informs us that he never received the letter from Dr. Adamson, and altogether it seems to us that there was great carelessness. That a patient suffering from small-pox can be sent home and left without medical attendance for a fortnight is most unsatisfactory.

WANTED—A HOME.

To the Editors of THE LANCET.

SIRS,—Can any of your readers kindly inform me if there is an institute where a female deaf mute, aged 16 years, could be educated in lip reading and also in some trade or occupation, and the probable cost and the length of time this would entail?

I am, Sirs, yours faithfully,

F. W. GUNN, M.D.Durh.

Widdrington, Northumberland, April 16th, 1902.

THE HABIT OF TIPPLING.

A CORRESPONDENT who writes above the frank signature "Dipsomaniac" tells a neat story in reference to the rapid growth of the habit of tippling which may develop in unsuspecting subjects. Two elderly ladies, he says, were surprised by a visitor in the act of drinking neat brandy. Upon his expressing some surprise they said that brandy had been recommended to them as a capital preventive against cholera and that first they took it with water and then they took it without water, and now they took it like water.

A MEDDLING CLERGYMAN.

Fairplay writes: "A is treating a man who is suffering from acute bronchitis. His condition becomes serious and a consultation is offered by A to the relations who refuse it, saying that they are satisfied that all possible has been done and that they want no other advice than they have had. A day after this the parish clergyman, who is calling daily, suggests the calling in of his intimate friend, Dr. B, another practitioner in the town, and states that he will pay the fee. (This to people who can well afford a fee.) This offer is refused and he is plainly told that the patient's friends desire no interference in that direction. The next day he again tries to persuade them to call in Dr. B without result. Has A a grievance?"

*** We speak on the facts as "Fairplay" presents them. He has a right to consider the clergyman officious. We recommend him to tell B that the instant his patient requires B's help, it will be asked for—and not before.—ED. L.

PROPOSED MEMORIAL TO THE LATE SURGEON-GENERAL W. NASH, A.M.S.

THE following subscriptions have been received since the last notification:—

THE CRAYON ANTI-BUÈE.

MESSRS. HAWKSLEY, of 357, Oxford-street, W., have forwarded to us a specimen of the crayon anti-buée which was described in our issue of March 1st, p. 589, by Dr. Walker Downie. Messrs. Hawksley inform us that the article is patented and sells for 2*s.* The use of the crayon undoubtedly does prevent the deposition of moisture upon laryngeal mirrors and the like. But soap does just as well when not made up into a crayon, as a correspondent pointed out in our issue of March 8th, p. 699, and a whole cake of soap can be bought for 6*d.*

◆

Dubitans.—1. The propriety of paying such visits depends upon the custom of the neighbourhood rather than upon the seniority of th medical man. It would be well if our correspondent consulted a prominent local practitioner as to the course he should adopt. 2. I is, in our opinion, incorrect for the holder of the diplomas in ques tion to prefix the title of "Dr." to his name on his door-plate an visiting-cards.

E.D.—In ordinary circumstances the medical officer of health, is no responsible for the actions of the sanitary inspector. The sanitar inspector is responsible to the sanitary authority who also appoin the medical officer of health.

Spes.—We have no knowledge of the treatment or remedy in question If our correspondent will send, or cause to have sent, to us a sufficien quantity of the remedy we will analyse it.

M. A. R. should apply to the Director-General of the Army Medica Service, 18, Victoria-street, S.W. The examinations are usually hel in February and August.

X. Y. Z.—The administrator of the anæsthetics should be paid by th medical man who has employed him.

ERRATUM.—In THE LANCET dated March 22nd, 1902, p. 835, a annotation appeared entitled "Light and Malaria." It was therei stated, in reference to the question how the parasite can b influenced by extreme temperatures, that "in the *American Journa of the Medical Sciences* for February Dr. A. F. A. King of New York puts forward an ingenious suggestion that the actual factor i question is the light, not the heat, of the sun," &c. Dr. A. F. A King should have been described as of Washington, D.C., and not o New York.

During the week marked copies of the following newspaper have been received:—*Yorkshire Post, Cardiff Mail, Sussex Dail News, Colchester Gazette, Lincolnshire Chronicle, Lincolnshire Echo, Belfast News Letter, Birmingham Post, Aberdeen Press, Folkeston Telegraph, Brighton Gazette, Surrey Advertiser, Bristol Mercury Dublin Express, Wiltshire Mirror, Bradford Observer, Morning Post, Essex Herald, Hereford Mercury, Daily Graphic, Sanitar Record, Local Government Chronicle, Mining Journal, Hertfordshir Mercury, Burton Chronicle, Lincolnshire Advertiser, &c.*

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (21st).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.) West London (2.30 P.M.), London Throat (2 P.M.).

TUESDAY (22nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

WEDNESDAY (23rd).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.).

THURSDAY (24th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

FRIDAY (25th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.). West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square, (9.30 A.M.), City Orthopædic (2.30 P.M.).

SATURDAY (26th).—Royal Free (9 A.M. and 2 P.M.), London (2 P.M.) Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.), Throat, Golden-square (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (21st).—SOCIETY OF ARTS.—8 P.M. Mr. R. T. Glazebrook: Glass for Optical Instruments. (Cantor Lecture.)

TUESDAY (22nd).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. Paper:—Dr. W. Ewart and Mr A. S. Morley: The Possibility of Recovery from the Active Stage of Malignant Endocarditis (illustrated by cases and specimens). Adjourned Discussion on the paper by Dr. F. J. Poynton and Dr A. Paine on a Contribution to the Study of Malignant Endocarditis.

WEDNESDAY (23rd).—SOCIETY OF ARTS.—8 P.M. Prof. S. P. Thompson: Opto-technics.

THURSDAY (24th).—DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND (20, Hanover-square, W.).—5 P.M. Meeting.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne-street, Edgware-road, W.).—8.30 P.M. Papers:—Mr. R. Johnson: Some Points in the Treatment of Tuberculous Disease of the Knee.—Dr. L. Guthrie: Congenital Hereditary Hæmaturia. Clinical Cases

FRIDAY (25th).—CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8 P.M. Exhibition of Clinical Cases followed by Discussion. Patients will be in attendance from 8 P.M. to 9 P.M.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (21st).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr A. Whitfield: Clinique. (Skin.)

TUESDAY (22nd).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. H. Campbell: Clinique. (Medical.)

WEDNESDAY (23rd).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. J. Clarke: Clinique. (Surgical.)

THURSDAY (24th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. Hutchinson: Clinique. (Surgical.)

FRIDAY (25th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. StClair Thomson: Clinique. (Throat.)

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach *THE LANCET Offices*, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Communications, Letters, &c., have been received from—

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

An Address

ON

THE DIAGNOSIS AND TREATMENT OF THE VARIOUS FORMS OF GOITRE.

Delivered before the Medical Society of Plymouth on March 8th, 1902,

By JAMES BERRY B.S. Lond., F.R.C.S. Eng.,

SURGEON TO AND LECTURER ON SURGERY AT, THE ROYAL FREE HOSPITAL, GRAY'S INN ROAD; SURGEON TO THE ALEXANDRA HOSPITAL FOR CHILDREN WITH HIP DISEASE.

Mr. President and Gentlemen,—All of us are brought at times into contact with cases of goitre and although in most instances the disease presents little or no difficulty as regards either diagnosis or treatment, yet occasionally we meet with cases that present the greatest difficulties in both respects. An accurate diagnosis of the exact nature of a goitre is essential before a correct opinion can be expressed as to prognosis and to the treatment that should be recommended No one who has seen a very early case of malignant disease of the thyroid can doubt that diagnosis may occasionally present great difficulties. No one who is suddenly brought face to face in the middle of the night with the patient suffering from acute suffocating goitre can doubt that efficient treatment is not always so easy as we should like it to be. No one who has had to remove a deeply seated goitre from behind the sternum of a patient who is in imminent danger of suffocation can doubt that the operative difficulties of thyroid surgery may be very considerable. All these have happened to myself and, I doubt not, to many of you, and any or all of them may happen to any of us

For purposes of discussion I propose to divide all thyroid swellings into four groups—(1) parenchymatous (bilateral) goitre, (2) encapsuled tumours (solid and cystic), (3) exophthalmic goitre, and (4) malignant disease—and to discuss each of them separately as regards both diagnosis and treatment.

I.—Parenchymatous (Bilateral) Goitre.

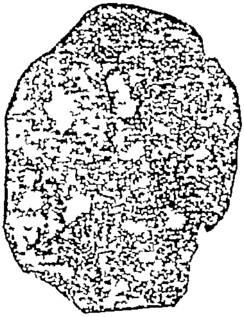
The parenchymatous goitre, the common goitre of young people, is a disease of the whole gland and therefore it affects all parts equally It causes a bilateral uniform swelling, the thyroid nature of which rarely admits of any doubt Its situation, its shape—preserving as it does the horseshoe shape of the normal gland—and the fact that it moves with the larynx on deglutition, prevent it from being mistaken for any non thyroidal swelling The only other thyroid swelling that presents all these characters is the goitre of Graves's disease (of which I shall speak presently) and certain very rare forms of inflammation and of malignant disease. Both of the latter usually have very distinct characters of their own. If the parenchymatous enlargement, however, be extremely slight it may be a little difficult to detect, especially if the patient be at all fat The best method of detecting very slight enlargements of the gland is to place the finger and thumb on either side of the lower part of the larynx and to direct the patient to swallow As the larynx rises it draws the thyroid gland upwards between the finger and thumb, which are thus enabled to judge of its exact size. Occasionally a thyroid gland is pushed forwards by some swelling behind it and may thus appear to be enlarged when it is not really so Thus a few months ago a middle-aged woman was sent to me on account of a slight swelling at the lower part of the front of the neck, it had been noticed for several months and was supposed to be a small goitre. There was also a history of dysphagia. On examination the thyroid gland was found to form a well marked visible, and easily palpable swelling which moved on swallowing but further investigation showed that behind the thyroid was a much deeper swelling which did not move on deglutition and which had displaced forwards the thyroid gland itself It was a carcinomatous tumour of the pharynx and œsophagus easily recognised by its extreme hardness and by examination of the interior of the throat.

A parenchymatous goitre is usually soft, but it is well to remember that it may also be exceedingly hard, so hard as to lead to mistakes in diagnosis. This hardness may be due in young adults to mere excess of thyroid secretion which fills up all the vesicles so tensely as to cause the whole gland to feel like a piece of wood. This kind of goitre is often associated with very severe dyspnœa and therefore it is well to remember that energetic treatment with iodine or thyroid extract will usually cause absorption of some of the secretion, softening of the gland and relief from the dyspnœa.

Parenchymatous goitres tend as they become old to undergo various secondary changes, one of the most important of which is fibrosis. The connective tissue between the vesicles develops at the expense of the latter This process may extend so far that eventually the whole gland presents little more than a mass of fibrous tissue. This extreme degree of fibrosis is, however, rare and is, I believe, never met with except in elderly people. Goitres in young people, however hard, are never composed to any large extent of fibrous tissue. I have often seen hard bilateral goitres in young people which had been diagnosed as "fibrous" but they have invariably proved to be parenchymatous goitres tensely filled with secretion.

The most extreme degree of hardness is met with in those goitres which have actually become calcified. Fig 1 shows a goitre from a woman, 87 years of age. It is composed mainly of fibrous tissue and in it are large areas of calcification.

Fig 1.



An old goitre from a woman, aged 87 years who died from sarcoma of the skull. It is composed chiefly of fibrous tissue with considerable areas of calcification. Reduced two-thirds. (Royal Free Hospital Museum. From a photograph by Miss M D French)

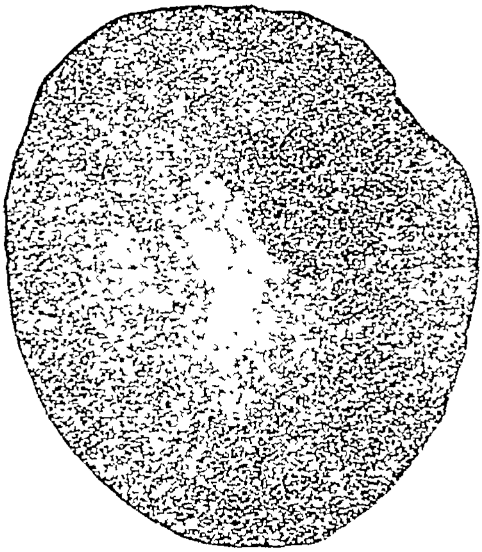
II.—Encapsuled Tumours (Solid and Cystic).

I come now to the second class of thyroid swellings—that of encapsuled tumours, solid or cystic. This is an extremely common form of goitre and certainly one of the most important from the surgical point of view since it is that which is most amenable to surgical treatment A very large proportion of the common goitres that we see in Switzerland, in Derbyshire, in Devonshire, and elsewhere consist wholly or partly of encapsuled tumours adenomata which have developed in the substance of the gland. They may be compared to the common adenomata of the breast or to the encapsuled fibroids of the uterus. These thyroid adenomata, composed at first of tissue closely resembling that of the thyroid gland in which they lie, have a remarkable tendency to undergo secondary changes They tend, on the other hand, to soften and to break down in the centre. The solid portions gradually melt away and disappear until the original solid adenoma has become converted into a cyst. On the inner wall of such a cyst traces of the original solid adenoma may often be seen adhering Such is the origin of the vast majority of thyroid cysts although it must be admitted that a small minority of them probably originate in another way and are not derived from pre-existing adenomata.

Another very common secondary change that is found in thyroid adenomata is fibrosis, the tumour being gradually converted into a mass of fibrous tissue, in the meshes of which are buried the remains of the glandular elements. If an old adenoma from a middle-aged or elderly person be examined it will often be found to contain in its centre a star shaped mass of dense fibrous tissue (see

Fig. 2). This fibrosis, beginning in the centre, gradually extends until more or less of the whole tumour has been converted into a dense, hard mass.

FIG. 2.



A solid adenoma of the thyroid, showing fibrosis commencing in the centre. From a woman, aged 42 years. Reduced five-sevenths. (Royal Free Hospital Museum. From a photograph by Miss M. D. French.)

It is well to remember that these hard fibrous adenomata containing small collections of epithelial cells present under the microscope some superficial resemblance to a carcinoma and I have more than once known perfectly innocent tumours of this kind described erroneously as malignant tumours and even published as such.

The diagnosis of a thyroid adenoma is usually a very simple matter, provided that the tumour is single and of sufficient size to be seen and felt. A swelling which is strictly unilateral, involving one or other lateral lobe exclusively, and which is not inflammatory or malignant, must, with certain very rare exceptions, be an encapsuled tumour, either cystic or solid—one, therefore, that is capable of removal by the operation of enucleation. The diagnosis between cystic and solid encapsuled tumours is often a matter of great difficulty, although generally not one of much practical importance, since the treatment is much the same in both. A tense cyst or a cyst with hard fibrous walls may be as hard as the very hardest solid adenoma. On the other hand, I have occasionally known surgeons of large experience to make a diagnosis of thyroid cyst from the extreme softness and apparent fluctuation, and to find at the operation that the tumour was solid throughout. He is a bold, and I venture to think a rash, surgeon who ventures to state definitely after physical examination of an encapsuled thyroid tumour that it is exclusively either solid or fluid.

Many unilateral thyroid tumours springing from the lower part of one lateral lobe, the commonest seat of thyroid tumours, tend, as they grow, to displace the trachea to the opposite side and to occupy themselves a situation in the middle line of the neck. Tumours in this situation, if small, may easily be mistaken for tumours of the isthmus itself, which are very rare. If large and occupying a considerable portion of the neck they may easily simulate bilateral parenchymatous goitres. They can be distinguished, however, by careful observation of the exact position of the trachea and larynx. The strictly parenchymatous goitre never displaces these organs from the middle line. The encapsuled tumour, springing from one or other lobe, always displaces them to a greater or less extent towards the opposite side. The rare tumour of the isthmus does not displace the trachea but as it necessarily forms a rounded prominent swelling, not involving the lateral lobes, there is little or no difficulty in its diagnosis.

A further point of distinction between large encapsuled tumours situated in the middle line of the neck and parenchymatous goitres is to be found in examining the upper border of the swelling. The encapsuled tumour has, of course, a convex upper border; the parenchymatous goitre presents a notch or depression marking the interval between the two lateral lobes.

Mixed forms.—Hitherto I have been speaking either of the purely parenchymatous goitre or of the single adenoma. The difficulties of exact diagnosis are very much increased when we come to that very common form of goitre in which one or more adenomata exist in an otherwise parenchymatous goitre, or to the equally common form in which the enlargement consists mainly of multiple adenomata, generally on both sides of the neck. It is usually a matter of great importance from the point of view of treatment to be able to say definitely how much of any given goitre consists of encapsuled tumour and how much of parenchymatous enlargement. I have already said that a strictly unilateral goitre is almost invariably an encapsuled tumour; I may go further and say that it is almost certain to consist of a single tumour, for multiple tumours affecting one lobe only of the gland, the opposite being quite healthy, are very seldom seen. Multiple tumours almost always affect both lobes of the gland, although generally to a different extent. Occasionally two tumours of the same size will occur in the two lobes, one on either side, and the resemblance then to a parenchymatous goitre may be considerable. The diagnosis must then be made chiefly by the shape of the swelling. The lobe that is enlarged by parenchymatous hypertrophy preserves its pyriform shape with the narrow end upwards. The encapsuled tumour is globular or perhaps oval, never strictly pyriform. It is frequently possible to detect at the upper and back part of the tumour a little conical process, the remainder of the lateral lobe, and this at once gives a clue to the nature of the case. But strictly symmetrical bilateral thyroid tumours are very rare. The common case is that in which one lobe is *much* larger than the other, and here there is seldom any doubt as to the existence of at least one encapsuled tumour.

Goitres are sometimes composed of a large number of adenomata or cysts, of comparatively small size, embedded in an otherwise parenchymatous goitre like plums in a plum pudding. If the parenchymatous matrix is small in amount the tumours may easily be felt; but sometimes they are deeply buried in a large mass of parenchymatous tissue. In the latter case, however, their diagnosis is not a matter of much importance, as the case will probably have to be treated as if it were one of pure parenchymatous enlargement. And here I should like to offer a word of warning and to say that a purely parenchymatous goitre occasionally presents a distinctly lobulated appearance. This may suggest that it is composed of a number of small tumours massed together when really there are no encapsuled tumours at all.

If the surgeon is in doubt as to the diagnosis between a parenchymatous and an adenomatous or cystic goitre and is proposing to operate upon it he will do well, if the case is not so urgent as to demand immediate operation, to administer iodine or thyroid extract for a few weeks. The parenchymatous goitre or portion of the goitre will probably under this treatment diminish in size, or at least become much softer. The tumours will be unaffected and, if embedded in parenchymatous tissue, will become relatively more evident as the parenchymatous tissue around them shrinks. Indeed, before undertaking the enucleation of any thyroid tumour a course of such medical treatment is often advisable, as the tumour is thereby loosened and its enucleation is facilitated.

III.—EXOPHTHALMIC GOITRE.

Of the remarkable disease known as exophthalmic goitre I need say but little on the present occasion. It is a subject that concerns the physician rather than the surgeon. Structurally this form of goitre differs widely from all others, presenting to the naked eye a firm, homogeneous appearance on section, with no visible vesicles and with little or no colloid. The absence of any vesicular or cystic structure and the absence of encapsuled adenomata serve to explain the fact that exophthalmic goitre rarely attains a large size and rarely causes serious tracheal narrowing. Microscopically it is composed almost wholly of proliferating thyroid epithelium. The diagnosis of a well-marked case presents no difficulties at all. In the very early stages, however, before the exophthalmos has become a noticeable feature, the goitre of Graves's disease may easily be mistaken for a simple parenchymatous one. It is very important not to make this mistake if any question of operation is under consideration. The removal of an exophthalmic goitre by operation is undoubtedly a far more serious matter than the removal of a parenchymatous goitre. Indeed, the circumstances which would justify such an operation are in my opinion exceptional. The diagnosis in the absence of exophthalmos should depend, I venture to think, more upon the general symptoms than upon the local characters of the goitre. The nervous fidgety manner of the patient, her restlessness and excitability, the moist skin, besides minor symptoms such as diarrhœa and local pigmentation, are of much value in the diagnosis. The nervous symptoms generally form a marked contrast to the usually rather dull and apathetic manner of a patient who is the subject of parenchymatous goitre. The persistently rapid pulse is, of course, a symptom of the greatest importance and if present with a uniform enlargement of the thyroid should always raise a strong suspicion of Graves's disease. Mere rapidity of pulse is not enough, however, for the establishment of the diagnosis in all cases, especially if the goitre be unilateral and deeply seated in the neck behind the clavicle or sternum. Goitres in this region are not infrequently accompanied by a somewhat rapid pulse. On several occasions on account of dyspnœa I have had to operate upon such cases in which an erroneous diagnosis of Graves's disease had previously been made by others mainly on the ground of rapidity of the pulse. Conversely it is well to remember that Graves's disease may become superadded to a previously simple form of goitre, and although the goitre of a *pure* case of Graves's disease presents always a symmetrical enlargement of all parts of the gland, yet a previously existing cyst or adenoma in one lobe may cause the goitre to assume a markedly asymmetrical shape and perhaps thus lead to an error in diagnosis.

IV.—MALIGNANT DISEASE.

Malignant disease in a well marked form when the growth has already penetrated the capsule of the thyroid gland does not usually present any great difficulty in diagnosis. The age of the patient, the rapid and steady growth of the tumour, its hardness, its irregular surface, its fixity, its tendency to infiltrate surrounding parts and to involve the recurrent laryngeal nerve, the carotid artery, the trachea, and the œsophagus, are common characteristics which leave but little room for doubt as to the diagnosis. At this stage, however, surgical treatment other than palliative is quite hopeless. If we are to do anything towards curing this terrible disease the diagnosis must be made early, while the disease is still confined within the gland, while there is still a possibility of complete removal of the tumour by a thorough operation. I will limit my remarks, then, to the diagnosis of the disease in this early stage.

In the first place malignant disease of the thyroid seldom occurs before the age of 40 years. The youngest patient who has come under my notice was a man, aged 25 years. But his was a very unusual case. A definite rule may be laid down that *when in the thyroid gland of a person over 40 years of age a tumour appears which is hard, which steadily and rapidly increases in size, and which is not of an inflammatory nature, the malignancy of such a tumour should be strongly suspected.* If, moreover, the surface of the tumour is irregular and bossy and if there is likewise dysphagia and pain in the neck, shooting up to the side of the head or to the shoulder, then the diagnosis is strongly confirmed. But there are several common innocent tumours of the thyroid which may simulate malignant disease. A simple cyst hitherto unnoticed may, from extravasation of blood or from inflammatory secretion into its interior, suddenly appear as a small hard lump. Not uncommonly such cysts cause at first a good deal of pain which adds to the difficulty of diagnosis. The roundness of the tumour and the smoothness of its surface are, however, the characters which will usually suffice for the diagnosis of a cyst. A cyst of this kind, moreover, does not steadily increase in size. It attains its full size in a few hours or in a day or two and afterwards either remains stationary or at most increases in size but very slowly. A very hard, intensely hard, nodular tumour may be found in the lower part of the thyroid of a person who says that he has only been aware of its existence for a few days. Such a tumour is probably an old calcified or fibroid nodule which has really existed for years but owing to its small size and deep situation has escaped notice. Many such cases have come under my observation. If there is any doubt as to its possible malignant nature a delay of a few days will show that the tumour is not increasing in size. Its free mobility will probably also point to the innocency of its nature.

There is a curious form of chronic painless inflammation of the thyroid which is not very uncommon in elderly women and which may be very difficult to distinguish from a slowly growing form of malignant disease unless an exploratory operation has been performed. Even after removal of the tumour and examination by the microscope the diagnosis is not always very clear. I have little doubt that some of the cases reported in literature as round celled sarcoma of the thyroid are really of this nature.

Malignant disease of the thyroid, as I have said, is almost always characterised by its hardness, but there is a rare form of sarcoma which is quite soft and is likely to be mistaken for a cyst, an abscess, or an extravasation of blood. The steady and rapid growth and the nodularity of the tumour are the most characteristic diagnostic features.

There are two somewhat rare forms of malignant disease of the thyroid which stand somewhat apart from the ordinary sarcoma and carcinoma and which run a much slower and less malignant course. One is the papilliferous cystic tumour, characterised microscopically by the presence of numerous delicate papillary intra-cystic growths. These tumours are analogous to the papilliferous tumours of the ovary. They have a great tendency to recur *in situ* and but little tendency to disseminate. Their clinical course often extends over many years and they are extremely suitable for operation, even when they have already attained a considerable size. Mr Arthur Barker has published a case of this kind in which the total duration of the disease was not less than 18 years. The first operation for the removal of the tumour was performed 10 years before the death of the patient. Another unusual form of malignant disease is that which is commonly known by the objectionable term of "malignant adenoma." By this term is meant a tumour which at first sight, and even after careful microscopical examination, appears to be innocent but which nevertheless is found to reproduce itself in distant parts of the body. The secondary tumours frequently present a very close resemblance in structure to that of the normal thyroid gland. I do not propose to enter now at any length into a discussion of this most interesting group of tumours. It includes several distinct forms. In some cases undoubtedly both the primary and the secondary tumours are to be regarded as malignant and it is well to remember that there is nothing unreasonable in supposing that the epithelium of a secondary growth can preserve both the characters and the functions of the epithelium of the gland whence it primarily came. Thus thyroid epithelium preserves the property of secreting colloid material whether it is in the thyroid gland or in a distant secondary tumour. Many of the primary tumours are undoubtedly cases of malignant disease in which the true structure of the tumour has been erroneously described. But there appears to be good reason for believing that some at any rate of the primary tumours have failed to disclose, even after careful microscopical examination by competent observers, any structural evidence of malignancy. The true pathology of this very interesting class of tumours has yet to be thoroughly worked out. At present it seems to me best to regard them all simply as malignant tumours of a peculiar nature.

TREATMENT

I have devoted most of the time at my disposal to the subject of diagnosis because the appropriate treatment of any given case of goitre must necessarily depend very much upon correct and accurate diagnosis. The principles which guide us in treatment are comparatively simple and their correct application is not difficult provided that our diagnosis is well founded.

In the first place we should look to the cause of the goitre and if the goitre is of the parenchymatous variety and is in an early stage, a good deal may be done for its cure by removing that cause. There is no doubt that a very large proportion of parenchymatous goitres, although not all, are due to the ingestion of a poison contained in the drinking water. We do not yet know what is the exact nature of that poison although we have abundant proof of the existence of a goitre-producing poison in certain waters. It is but reasonable then, to inquire into the quality and source of the water that the patient drinks and if possible to substitute for it a purer and better water. But these remarks must be held to apply only to early cases of parenchymatous goitre. In the case of cystic and adenomatous goitres and old parenchymatous ones in which secondary changes, such as fibrosis, have occurred it is useless to expect benefit from a mere change of water-supply. I do not propose to enter into that most interesting and fascinating subject of the essential cause of goitre, much as I should like to do so.[1]

Drugs in the treatment of goitre.—With regard to the use of drugs in the treatment of goitre it is naturally chiefly in the early stages of the parenchymatous form of the disease that we may expect most benefit from their use. In the case of cysts and of old parenchymatous goitres which have undergone much secondary change they are of little or no value. Encapsuled adenomata are seldom affected by drugs, but I have some reason for believing that very soft adenomata in young people are to a certain extent beneficially influenced by their administration.

The two drugs which stand in the first rank, far above all others, in the medical treatment of goitre are, of course, iodine and thyroid extract and I need do no more than mention them. I need likewise only mention external applications, such as tincture of iodine, which are sometimes useful, especially if applied freely; iodine is absorbed and acts just as if it had been taken internally.

Removal of goitre by operation.—I now come to what is from the surgical point of view the most important method of treatment—namely, removal by operation. I need hardly remind you that operations for the removal of goitre may be divided in the main into two, an extra-capsular operation known as extirpation, and an intra-capsular, or more properly an intra-glandular, operation known as enucleation. In the first the operator keeps outside the capsule of the gland, ties all vessels before they are cut, and, in short, makes a careful, deliberate dissection. He must see exactly what he is doing at each step of the operation and he must take special care not to wound the various important structures, such as the recurrent laryngeal nerve, the jugular vein, &c., which lie in immediate contact with the thyroid gland. In the enucleation operation the surgeon must cut into the gland itself until he comes to the surface of the encapsuled tumour, and then with blunt instruments he proceeds to enucleate the tumour from the glandular bed in which it lies.

Now enucleation is suitable only for encapsuled tumours and it is very important to bear this in mind. In the last few years this operation has become very popular and I notice a tendency in certain quarters to perform it in cases that are not really suitable for it. If properly performed upon a suitable case it is an operation attended by scarcely any risk. But if attempted in an unsuitable case it is by no means free from risk, and especially from risk of hæmorrhage. In enucleation, as ordinarily performed, the tumour is shelled out more or less rapidly, no attempt being made to stop the hæmorrhage until the tumour has been removed. In some of my earlier operations, when I had had but little practice in enucleation, it happened occasionally that a good deal of blood was lost, chiefly from delay in getting the tumour out or from attempting to perform a simple enucleation in cases of very large tumours, which are more suitable, in my opinion, for the modified operation of resection-enucleation. In the latter operation the hæmorrhage is much more under control because most of the main vessels are tied or clamped before the tumour is enucleated. Although I have never in any of my own enucleation operations known hæmorrhage to be so severe as to threaten life, yet I have seen deaths from this cause in the hands of others and have from time to time heard of other such cases. Probably in nearly all these cases the excessive hæmorrhage was due to the enucleation having been attempted in cases in which no enucleable tumour was present, or in which the tumour was so large that it ought to have been dealt with by some modification of the operation such as I have mentioned.

I observe that within the last month the senior surgeon of one of the London hospitals, in some clinical remarks upon a case of goitre, draws attention very rightly to the danger of hæmorrhage during the operation of enucleation. In the course of his remarks about his case, however, he tells us that the patient was a girl, aged 16 years, with an obvious enlargement of the whole gland, one half being larger than the other, and being composed of several nodular masses. He goes on to say that he would have no hesitation in selecting enucleation as the operation to be performed. If this is the kind of case for which enucleation is recommended without hesitation I am not at all surprised that he is impressed by the seriousness of hæmorrhage.

Multiple enucleation adds considerably to the severity of the hæmorrhage if the tumours are at all large. The older the adenoma or cyst the more likely is it to have a tough thick wall, and the more easy will it be therefore to enucleate. I remember on one occasion being able to enucleate an old cyst as large as a goose's egg in a man, aged 64 years, without having to tie a single vessel. But this is very unusual. Solid adenomata in young people, especially if embedded in a considerable amount of parenchymatous goitre, are often difficult to enucleate, as hæmorrhage is apt to be profuse and as the wall of the tumour is frequently very thin and not always easy to recognise. It is often better under these circumstances to do a simple extirpation of one lobe rather than run the risks of an enucleation.

It will be gathered from what has been said that I consider extirpation, or its modifications, resection, or resection-extirpation, to be the proper operation for cases of parenchymatous goitre demanding any operation; for those cases also in which there are many cysts or adenomata distributed throughout the gland it is generally to be preferred to enucleation.

In the great majority of cases of parenchymatous goitre no operation at all is desirable. Either the goitre is amenable to medical treatment or it does not cause sufficient trouble to warrant the performance of so severe an operation as extirpation. For mere deformity I hold that extirpation of a parenchymatous goitre is unjustifiable, except possibly in certain very exceptional cases. It is dyspnœa, and especially increasing dyspnœa, which does not yield to medical treatment, that calls for this operation. The more severe the dyspnœa the more urgently is the operation demanded. In young people serious dyspnœa occasionally supervenes very rapidly. A remarkable case of this kind occurred to me last summer. A girl, aged 14 years, was sent to me by Dr. Herbert Tilley on account of a parenchymatous goitre which had been noticed only three weeks. In spite of energetic medical treatment the dyspnœa had steadily and rapidly increased. A few hours after I first saw her I received an urgent telephone message to say that she was suffocating. On my arrival she was deeply cyanosed and already unconscious. Fortunately, everything had been prepared for operation, so I immediately took up a knife and cut right down upon the goitre as she lay there in bed. Inserting a forefinger behind the left lobe I drew this forcibly forwards so that in less than two minutes from the beginning of the operation the pressure upon the trachea had been relieved. I was then able quietly and deliberately to remove the whole of that lobe and about one half of the opposite one. It was seen that the lateral walls of the trachea were actually in contact, so that the only space available for breathing was a very small chink at the anterior part. The goitre was purely parenchymatous, was about as large as an orange, and was largely substernal. The patient did not regain consciousness until an hour after the operation had been finished. She never moved during the operation and afterwards she told me that she had not the slightest recollection of my arrival or of any operation having been performed. She made a rapid and excellent recovery and when I last saw her, two days ago, she was found to be in perfect health in every respect.

There are two classes of goitre in which dyspnœa is apt to supervene very quickly and to be a very serious danger to life. One is the rapidly-growing goitre of girls and boys at the age of puberty, such as that which I have just described. The other is that in which there is a small deeply-seated swelling, generally an encapsulated tumour, lying behind the clavicle or the sternum. Patients with the latter kind of goitre are almost invariably adults. A swelling in this situation is likely to become suddenly displaced into the upper opening of the thorax and to cause most dangerous dyspnœa. Or such a tumour may suddenly become enlarged from inflammation or more commonly from hæmorrhage into its interior. Several instances of both these occurrences have come under my notice. These tumours are generally easily and most satisfactorily treated by enucleation, however deeply they may be situated.

In enucleation, as in extirpation, it is almost always dyspnœa that calls for the operation; occasionally it is dysphagia, especially in the case of small tumours projecting from the back of the gland and pressing upon the œsophagus and pharynx. For mere deformity it is quite justifiable to perform an enucleation, if the patient desires it, provided that the operator is certain that the operation can be easily performed with little or no risk to life.

Time prevents me from entering at any length into the subject of the surgical treatment of exophthalmic goitre and of malignant disease. With regard to the former I would only say that the cases in which removal of any part of the goitre is advisable must be very exceptional. Occasionally benefit can be obtained from ligature of two or three of the thyroid arteries, but it must be remembered that even this operation is by no means devoid of danger. With regard to the practice of cutting or excising the cervical sympathetic nerve for Graves's disease I look upon it as wholly unjustifiable. Founded upon an entirely erroneous view of the pathology of the disease, uncertain and often most dangerous in its results, it has in my opinion nothing whatever to recommend it.

---

[1] I have elsewhere discussed this subject at some length. See "Diseases of the Thyroid Gland and their Surgical Treatment," J. and A. Churchill, 1901, Chapter V.

Malignant disease of the thyroid is seldom seen early enough to permit of any operation for its removal. It must be treated on the general principles that guide us in the treatment of malignant disease elsewhere. If there is a reasonable prospect that the whole of the disease can be removed by an operation that will not kill the patient or leave him after recovery worse than he was before the operation, then it should be undertaken If it is impossible to remove the disease—and this is generally the case—then something may be done to relieve urgent symptoms, such as dyspnœa, dysphagia, and pain The surgeon who undertakes to remove a malignant goitre the diagnosis of which is no longer doubtful must be prepared to meet with considerable difficulties. If the removal is to be satisfactorily accomplished he must be prepared to perform, if necessary, some very large operation, including perhaps such a severe proceeding as resection of a portion of the internal jugular vein or carotid artery, or even parts of the trachea or œsophagus Whether these very extensive operations are really worth doing seems to me very doubtful. On the other hand, the removal of a malignant goitre in its *early* stage while the tumour is still confined within the capsule presents little difficulty and is often a much less serious proceeding than the extirpation of many an innocent goitre.

CONCLUSION.

And now, gentlemen, I must conclude what has been, I fear, a somewhat lengthy address. I trust that I have not seemed to be too dogmatic in what I have ventured to say. I have expressed to you freely my own opinions which I have formed on this subject after an experience which I think I may fairly claim to have been tolerably extensive. You will probably wish to know what the results of my operations have been. Without going into details, I may say, briefly, that the total number of all my operations for the removal of goitre of all kinds is 155 Among the earlier operations, or, to be strictly correct, among the first 46, there were four cases of death The only death in the last 109 cases was that of a woman who was admitted to the Royal Free Hospital with much cyanosis, a large and partly substernal goitre, and signs of an intrathoracic tumour of uncertain nature. After a consultation with my medical colleagues I performed an exploratory operation and removed the substernal portion of the goitre. The wound ran a normal aseptic course but the dyspnœa and cyanosis were not relieved. When the patient died, rather more than three weeks after the operation, it was found that the dyspnœa was due to a sarcomatous tumour of the root of the lung and mediastinum secondary to a small primary growth of the abdomen This death is also the only one that has occurred to me after any enucleation operation. the total number of which amounts at the present time to exactly 100.

HEALTH OF HEAVITREE, EXETER.—Dr. J F. Wolfe, the medical officer of health, in his annual report to the Heavitree Urban District Council states that during 1901, on an estimated population of 7527, there were 130 births registered, equal to a rate of 17 19 per 1000 The total number of deaths was 114, equal to a rate of 15·08 per 1000

VACCINATION REGULATIONS —At the meeting of the Helston Board of Guardians held on March 29th a letter was read in which the Local Government Board replying to a communication from the guardians stated that the Board of Guardians had no power to appoint public vaccinators for primary vaccinations only or to pay its public vaccinators lower fees than those fixed by the Vaccination Order of 1898, but if revaccinations were likely to be numerous in the Helston Union the Board had no objection to the appointment of suitable stations for the performance of revaccination and to the payment of half-a-crown to the public vaccinator for each case performed there.

The Milroy Lectures

ON

THE ETIOLOGY OF TYPHOID FEVER AND ITS PREVENTION.

Delivered at the Royal College of Physicians of London on Feb 20th, 25th, and 27th, 1902,

BY W. H. CORFIELD, M.A., M.D. OXON.,
F.R C.P. LOND.,

PROFESSOR OF HYGIENE AND PUBLIC HEALTH AT UNIVERSITY COLLEGE, LONDON; CONSULTING SANITARY ADVISER TO HIS MAJESTY'S OFFICE OF WORKS.

LECTURE III.[1] (*concluded*)

Delivered on Feb 27th, 1902

I HAVE already stated the opinions of some of the most eminent writers on the subject with regard to the question of the communication of typhoid fever directly from one person to another—that is, through the medium of the air—but I will now proceed to cite some instances in which the disease is evidently spread to a considerable extent by means of direct contagion Dr W Budd in his admirable treatise already referred to gives a long account of an outbreak of the disease which he investigated in the village of North Tawton in Devonshire, where he lived and was in almost exclusive possession of the field as a medical practitioner. In the first place he points out that in this village "privies, pig-sties, and dungheaps continued hour after hour to exhale ill odours without any subsequent effect on the public health" and states that he "ascertained by an inquiry conducted with the most scrupulous care that for 15 years there had been no severe outbreak of the disorder and that for nearly 10 there had been but a single case. For the development of this fever a more specific element was needed than either the swine, the dungheap, or the privies were in the common course of things able to furnish In the course of time, as was indeed pretty sure to happen, this element was added and it was then found that the conditions which had been without power to *generate* fever had but too great power in promoting its spread when once the germ of fever had been introduced. On July 11th, 1839, the first case of typhoid fever occurred in a poor and crowded dwelling. Before the beginning of November in the same year more than 80 of the inhabitants had suffered from it under my care." He then describes the course of the outbreak, showing quite clearly over and over again that one person contracted the disease from another. Later in his book, after having mentioned some other outbreaks and quoted various authors to prove that the disease is contagious, he refers to North Tawton again as follows. "About two years ago—i e., in 1873—after an interval of 30 years' almost entire immunity this town was again visited by typhoid fever. Meanwhile a water company had been established by means of which drinking-water, brought from a considerable distance in iron pipes, is delivered under high pressure to every inhabitant. Contamination of this water by human excreta is an absolute impossibility, and yet in these two outbreaks of typhoid the population suffered even more severely than before In the course of a few months out of a population of 1500 persons 120 were known to have had typhoid fever and 11 of their number died." He considers that in this and in some other epidemics which he describes "the air was the great medium through which the infection passed." His final opinion as to the relative importance of water and air as media for communication of the poison of the disease is stated as follows. "The exact proportion which the cases caused by infected water bear to those caused by infected air is not easy to determine and probably varies much under different conditions of soil, climate, season, water-supply, social habits, and sanitary arrangements. As far as my own experience goes I can state that the worst and most widespread outbreaks which I have ever witnessed occurred in communities where the drinking-water was absolutely blameless."

---

[1] Lectures I and II., and the first portion of Lecture III. were published in THE LANCET of March 22nd (p. 793), April 5th (p. 912), 12th (p. 1013), and 26th (p. 1155), 1902, respectively

Dr. J. Niven, medical officer of health of Manchester, says: "It is also necessary to remember that, given certain conditions, such as crowding in a household, typhoid fever is terribly infectious," and he gives three remarkable instances, one being that of a number of nurses in a public institution among whom it was introduced by one of their number and who took it from one another, as he was able "at once to dismiss the water and milk and also any condition affecting the drainage of the wards." None of the patients in the institution took it. (*Public Health*, vol. iv., p. 202.)

In the twenty-fourth annual report of the State Board of Health of Massachusetts for 1882 Dr. William T. Sedgwick, after attributing the epidemics at Lowell and Lawrence to polluted water, reports on three epidemics in Bondsville, Provincetown, and Milleville, each of which he attributes to "secondary infection," having excluded infection by means of water and milk. He gives a graphic account of the way in which the poison of the disease gets handed about, and says, "It is easy for me to understood how dirt, diarrhœa, and dinner too often get sadly confused. Personal filth is apparently the principal agent of secondary infection." Of the epidemic at Milleville he says, "The high mortality was probably due not so much to the severity of the disease as to utter neglect and dire poverty. The local conditions were very bad, and the people were mostly very poor. The circumstances favoured the spread of the disease by secondary infection, and to that, in my opinion, the epidemic was almost wholly, if not entirely, due."

As an instance of direct contagion I may mention that Dr. H. F. Parsons reported on an outbreak of typhoid fever at Bedlingtonshire (Northumberland) when there was endemic prevalence of the disease in a colliery district in 1889. He found that most of it was referable to "a case which occurred in a close, confined, and filthy part of Bedlington town. The disease first spread to other families living in tenements under the same roofs and then in the neighbouring streets, where want of air-space, privy and drain nuisances, and general want of cleanliness prevailed. Dr. Parsons reported in 1892–93 on a severe but circumscribed outbreak of typhoid fever which occurred at Newfield Moira (Leicestershire) extended over two months and was limited to two rows of houses. The first cases were possibly contracted in Burton-on-Trent. The spread of the fever was not due to polluted water or milk nor to defects of drainage or common use of privies but was "probably due to direct contact with specific infection favoured by common use of wash-houses, foul state of unpaved yard, and careless habits of mining population."

In the same year Dr. R. D. Sweeting reported on an outbreak at Temple Cloud, Cameley parish (Somerset). In this district the early cases were "associated with grossly unwholesome circumstances of water-supply and excrement disposal," but the later cases were "probably directly infected from the earlier owing to non-disinfection of stools."

Dr. Sweeting reported in 1893 on a localised outbreak of typhoid fever occurring during the first four months of the year on the outskirts of the town at Amlwch (Anglesea). He found that there was no common water-, milk-, or food-supply, and no drainage, but that the "disease spread from an imported case amongst tenants and visitors in the absence of proper nursing, isolation, and disinfection."

In 1895 Dr. S. W. Wheaton reported on a remarkable outbreak of typhoid fever at Quarry Bank (Staffordshire). This outbreak was almost entirely confined to a small portion of the district and especially to one particular street. "This marked localisation of the fever and the fact that it had in some instances affected nearly all the members of certain families, suggested the presence of some fever (e.g., typhus fever) more directly contagious from person to person than enteric fever. The fever in question was found to be undoubtedly typhoid fever. The water-supply was in most instances from draw-wells subject to pollution by leaking privies, defective drains, and by surface washings." The spread of the disease was "probably in part due to polluted water, partly to privies which had become infected, and to *personal contagion*." (The italics are mine.)

In 1895 Dr. H. T. Bulstrode reported on an outbreak occurring at Pottersbury (Northamptonshire) which commenced in July and was still continuing at the date of the report in November. The evidence pointed to "polluted well water as a very important factor in causation, *though personal infection had probably considerable influence in the spread of the disease*."

In 1895 Dr. G. S. Buchanan reported on the continue prevalence of typhoid fever at West Bromwich (Staffordshire for several years. In 1895 there was a heavy incidence of the disease on three small areas widely separated one from another. The prevalence of the fever was "referred to the many opportunities of local spread from patients or invaded premises afforded by sanitary defects and by want of isolation hospital accommodation."

In 1899 Dr. S. M. Copeman reported on an outbreak at Shirebrook village (Derbyshire) that the disease was "*mainly spread by personal contact*, though in addition there appeared reason for suspecting that the milk-supply was concerned in causing extension of epidemic."

In August, 1900, Dr. Copeman reported on an inquiry into the continued prevalence of typhoid fever at Shirebrook, in the Blackwall Rural District, on the borders of Nottinghamshire and Derbyshire. He found "that the annual recurring outbreaks of typhoid fever in Shirebrook have been in large measure dependent upon the polluted condition of the subsoil in the lower portions of the village arising from the impossibility of securing efficient isolation in the cottages. In the newer colliery village, situated as it is on considerably higher ground, typhoid fever had not made its appearance before 1899. In this portion of Shirebrook also the disease was undoubtedly spread by personal infection, although in addition question arose as to whether the consumption of infected milk may not have played a part in the extension of the disease."

Dr. J. Priestley, the medical officer of health of Lambeth, in 1898 reported that in that parish in three instances typhoid fever was conveyed from person to person during nursing.

In his annual report for 1900 as medical officer of health of the London County Council Mr. Shirley Murphy gives the following cases of infection from one person to another in different districts in London: "Dr. Reginald Dudfield observed this in four instances; Dr. Parkes shows the extension of the disease in Chelsea from one person of a family to seven others; Dr. Sykes gives account of two households in St. Pancras, in one of which the first case of the disease was followed by six others, and in the second by nine others; Dr. Newman connects directly or indirectly nine cases in Clerkenwell with one or other of three cases occurring among children attending the same Sunday school; Dr. Bryett gives particulars of six series of such cases occurring in Shoreditch; Dr. Kempster attributes a group of cases occurring in a street in Battersea to the same cause; and Dr. Bond mentions two nurses who were infected while in attendance upon cases of the disease."

An important paper was read before the Epidemiological Society in 1900 as an introduction to a discussion on the Infectivity of Enteric Fever by Dr. E. W. Goodall, medical superintendent of the Eastern Hospital of the Metropolitan Asylums Board. Dr. Goodall, who has had exceptional opportunities of studying the disease, has come to the conclusion that, contrary to the opinion of many high authorities, the view held by Bretonneau, Trousseau, Gendro Piedvache, Budd, Sir Thomas Watson, and Dr. Alexand Collie, the former medical superintendent of the Homerto Hospital, the disease is directly infectious from one person to another is the correct one. He insists on the frequency with which those in attendance on the sick catch the disease, produces a number of instances of this having taken place among the nurses of the Metropolitan Asylums Board Hospitals, states that "enteric fever has attacked the staff in the three newest hospitals of the Asylums Board—the Brook, the Park, and the Grove," and adds: "Concerning the 10 cases at the Brook Hospital Dr. J. MacCombie has kindly informed me that five of them occurred in the persons of nurses working in the enteric fever wards, including an assistant nurse who came straight from the Broughton Sanatorium where she had been nursing enteric fever patients and who joined the Brook Hospital during the incubation stage of the disease, while of the other five, two were men whose duty it was to keep the floors of the enteric fever wards polished. With respect to the three cases at the Grove, the most recently erected hospital, I am indebted to Dr. J. E. Beggs for the information that they were two assistant nurses and a wardmaid, all of whom for nearly two months had worked in enteric fever wards. It was the duty of the wardmaid to carry the soiled linen to the tank." He agrees with Dr. Collie's opinion, "that if enteric fever amongst the staff of a hospital is to be attributed to faulty sanitary arrangements, especially in connexion with the drainage, we should find the disease occurring more frequently amongst the patients who are not suffering from the fever than appears to be the case." With regard to the fact that other patients do not, as a rule, catch typhoid fever from patients suffering from that disease (although I am satisfied that they occasionally do so), he points out that it is rare, even for typhus fever, which everybody deems to be highly infectious, to be caught by one patient from another in a fever ward, and he concludes. "Personally I am strongly inclined to side with those who hold that enteric fever is much more readily and directly communicable than is commonly supposed."

In the discussion which followed Dr F Foord Caiger, medical superintendent of the South-Western Hospital, stated that the contagiousness of typhoid fever to those "who are in the daily administration of a fever hospital into which enteric fever is admitted has become a matter of conviction" and he stated that in the South-Western Hospital, "in the course of nine years during which enteric fever has been admitted there, 23 members of the staff have contracted it and three of them have died Of these 23 members every one was a nurse and, with one exception, every one of these nurses was nursing in the enteric fever wards. When you consider that the proportion of enteric fever nurses to the whole of the nursing staff is only like one in 15 this fact is very striking."

Dr. Bulstrode is of opinion that "the view is certainly gaining ground that enteric fever is more directly communicable from the patients to the nurses and attendants than was formerly supposed"

Dr Alfred Hill of Birmingham and Dr Niven of Manchester are of the same opinion. The latter traced 53 cases out of 484 to direct infection.

Dr P Manby quoted an interesting instance of communication of typhoid fever from one person to another in an hotel, and Dr Franklin Parsons, the President of the Society, one of the medical inspectors of the Local Government Board, gave several instances in his own experience in which, after careful investigation, "personal communication seemed the only agency" to which the disease could be attributed, and as the result of his great experience Dr Goodall says: "I am quite sure that those are wrong who teach as is evidently taught by the leading text-books that there is no risk in nursing typhoid fever patients and that there is no necessity for removing an enteric fever patient from his home to hospital." In fact, the result of this discussion showed that there was great unanimity of opinion, not only among the inspectors of the Local Government Board, but among medical officers of health throughout the country, that communication by direct contagion is a much more common cause of the spread of typhoid fever than is commonly supposed

We now come to the consideration of the actual poison of the disease. I will first give you Mr (afterwards Sir John) Simon's views in his own words. He said in his supple*mentary report for 1873*, "While, however, *thus far there* is only the familiar case of the so-called *common chemical poison*, which hurts by instant action and in direct proportion to its palpable and ponderable dose, the other and far wider possibilities of mischief which we recognise in filth are such as apparently must be attributed to *morbific ferments* or *contagia*, matters which not only are not gaseous, but on the contrary, so far as we know them, seem to have their essence, or an inseparable part of it, in certain solid elements which the microscope *discovers in them—in living organisms, namely, which in* their largest sizes are but very minute microscopical objects, and at their least sizes are probably unseen even with the microscope, organisms which in virtue of their vitality are indefinitely self-multiplying within their respective spheres of operation, and which, therefore, as in contrast with common poisons, can develop indefinitely large ulterior effects from first doses which are indefinitely small.

"As, apparently, it is by these various agencies (essential and incidental) that filth produces 'zymotic' disease, it is important not to confound them with the fœtid gases of organic decomposition, and the question what infecting powers are prevalent in given atmospheres should never be regarded as a mere question of stink It is of the utmost practical importance to recognise in regard of filth that agents which destroy its stink may yet leave all its main powers of disease *production undiminished Whether the* ferments of disease if they could be isolated in sufficient quantity would prove themselves in any degree odorous is a point on which no guess need be hazarded, but it is certain that in doses in which they can fatally infect the human body they are infinitely out of reach of even the most cultivated sense of smell, and that this sense (though its positive warnings are of indispensable sanitary service) is not able, except by indirect and quite insufficient perceptions, to warn us against risks of morbid infection."

And further, in the same report "It must be remembered that gases on the one hand and the particulate ferments on the other stand in widely different relations to air and water as their respective media of diffusion. The ferments, so far as we know them, show no power of active diffusion in dry air, diffusing in it only as they are passively wafted and then probably, if the air be freely open, not carrying their vitality far, but as moisture is their normal medium currents of humid air (as from sewers and drains) can doubtless lift them in their full effectiveness, and if into houses or confined exterior spaces then with their chief chances of remaining effective, and ill-ventilated low-lying localities, if unclean as regards the removal of their refuse, may especially be expected to have these ferments present in their common atmosphere as well as, of course, teeming in their soil and ground water Considerations like some which I have stated in regard of infective air apply equally to infective water In the latter, just as in the former, the zymotic *malignity is but indirectly and most imperfectly suggested* to us by qualities which strike the common sense, or by matters which chemical analysis can specify As any unbrutalised sense of smell will turn with disgust from certain airs, so will it, and common taste and sight, be repelled by certain waters, and as the chemist can show certain foulnesses in the one, so he can show certain foulnesses in the other, but these tests, it must always be remembered, are tests only of the most general kind Confessedly they do not touch the *corpus delicti*, but only certain conditions to which it is or may be collateral, and their negative findings are consequently not entitled to the same sort of confidence as their positive Chemical demonstration of unstable nitrogenous compounds in water is a warning which of course should never be disregarded; but till chemistry shall have learnt to identify the morbific ferments themselves, its competence to declare them absent in any given case must evidently be judged incomplete, and waters which chemical analysis would probably not condemn may certainly be carrying in them very fatal seeds of infection."

Mr Simon continues "Since the year 1849, when Dr. (now Sir William) Jenner made known his conclusive and masterly discrimination of this specific form of fever, successive studies have tended with singular uniformity to connect it in regard of its origin with nuisances of an excremental sort [3] In illustration of that fact in the natural history of enteric fever I may refer to an abstract which I append of the experience of the Medical Department during the four years 1870–73 in this particular branch of disease-production, and such illustrations might be multiplied to any desired extent The experience is, not only that privies and privy-drainage, with their respective stinkings and soakings, and the pollutions of air and water which are thus produced, have in innumerable instances been the apparent causes of outbreaks of enteric fever, but, further, that they have seemed capable of doing this mischief in a doubly distinctive way, first, as though by some aptitude which other nuisances of organic decomposition, though perhaps equally offensive, have not seemed equally or nearly equally to possess; and secondly, as though this specific property, so often attaching to them in addition to their common septic unwholesomeness, were not, even in them, a fixed property The explanation of this experience, the explanation of the frequent but not invariable tendency of privy nuisances to infect with enteric fever, has seemed to consist in the liability of such nuisances to carry with them, not invariably, but as frequent accidental adjuncts, the 'specific' contagium of any prevailing bowel-infection, for presumably the privies of a population receive (*inter alia*) the diarrhœal discharges of the sick; and it has long been matter of fair pathological presumption that in any 'specific' diarrhœa (such as eminently is enteric fever) every discharge from the bowels must teem with the contagium of the disease. Medical knowledge in support of this presumption has of late been rapidly growing more positive and precise, and at the moment of my present writing I have the gratification of believing that under my lords of the Council it has received an increase which may be of critical importance in a discovery which seems to give us for the first time an ocular test of the contagium of enteric fever; in the discovery, namely, of microscopical forms, apparently of the lowest vegetable life, multiplying to innumerable swarms in the intestinal tissues of the sick, penetrating on the one hand from the mucous surface into the general system of the patient, and contributory on the other hand, with whatever infective power they represent, to the bowel contents which have presently to pass forth from him" (Report of the Medical Officer of the Privy Council and Local Government Board, New Series, No. II., 1874)

---

[3] The very able writings of Dr Murchison, dating from a paper by him in the Medico-Chirurgical Transactions of [illegible], have been of particular influence in that contention.

The investigations referred to by Mr. Simon were those made by Dr. Klein in his report on the Intimate Anatomical Changes in Enteric, or Typhoid, Fever in the report of the medical officer of the Privy Council and Local Government Board for 1874 (New Series, No. VI.). In this report Dr. Klein described the changes in various organs in typhoid fever, giving a number of plates in illustration of these changes and also described certain organisms found in the intestinal mucous membrane and some other organs in the early stages of the disease. After this other observers described various organisms found in the organs in fatal cases of typhoid fever, especially Klebs who announced the discovery of a long thread-like bacillus which he considered to be the cause of the disease, and in 1880 Eberth discovered the rod-shaped organism now known by his name as Eberth's bacillus, or the bacillus typhosus. It appears, however, that before Eberth's paper appeared Koch had found in about half the number of cases examined by him typical colonies of short bacilli precisely similar to those afterwards described by Eberth. It would appear, therefore, that Koch first discovered the true bacillus typhosus, although his name has not become associated with it. This bacillus was subsequently investigated by Dr. Gaffky, whose paper was published in the *Mittheilungen aus dem Gesundheitsamte*, vol. ii., 1884, and a translation of it by Dr. Pringle was published by the New Sydenham Society in its volume for 1886. Dr. Gaffky examined the organs of 28 fatal cases of typhoid fever and found the typical bacillar masses in 26 of them. He says: "My results agree entirely with the descriptions given by Eberth, Koch, and Meyer in regard to the shape and appearance of the bacilli. On the average they are about thrice as long as they are broad; their length corresponds to about the third part of the diameter of a red blood corpuscle. In isolated spots one may see somewhat longer threads which on more thorough examination can, however, be seen to be made up of several members. Trifling differences in breadth occur even in different cases in the same epidemic, but this appearance is to be referred only to the greater or less intensity of the staining of the sections; at least, I have never been able to observe it in preparations on cover-glasses in which the staining is always deep; the extremities of the bacilli are distinctly rounded off. In several of the cases I examined the bacilli found in the internal organs contained unmistakable spores which appeared as round portions, remaining unstained, and occupying the whole breadth of the bacilli."

In discussing the questions as to whether these typhoid bacilli are specific pathogenic organisms he says: "If I range myself on the side of those who consider the typhoid bacilli as specific organisms and their origin from putrefactive bacilli as at least very improbable it is upon the following grounds. In almost all the cases of typhoid fever which I have examined, whether they came from Berlin hospitals, from St. Petersburg, or from Wittenberg, there was always present a definite form of rod-shaped organism in the internal organs, arranged in quite a characteristic manner, and undoubtedly the same as had previously been observed at various times and in various places by Eberth, Koch, Meyer, and O. Friedländer. Anatomical examination gives us not the slightest ground for thinking that these bacilli had anything whatever to do with putrefaction. To all appearance they did not proliferate after death, as one does not find that the masses are at all more numerous or larger in cases in which putrefaction has already set in than in those examined as soon after death as possible. Further, in an organ removed as early as possible from the body, although it may contain ever so numerous masses of bacilli, all coarse signs of commencing putrefaction perceptible to the senses are wanting. In the same way the microscopic appearance of the tissue presents nothing suggestive of that process. The nuclei in the vicinity of the masses stain rather exceptionally deeply with aniline stains, whilst the bacilli themselves (apart from the conditions found in the intestine) always form limited masses and never permeate the organ in all directions, as we are accustomed to see in the case of putrefactive bacilli. I would also adduce as a very weighty argument against the view that typhoid bacilli have any connexion with putrefaction the fact that when cultivated outside the body they never become causes of putrefaction, as far as my researches permit of a judgment. I have carried out a great number of cultivations in succession with those derived from 13 different cases and the bacilli never produced putrefaction in substances extremely liable to putrefaction in spite of their luxuriant growth. Even when cultivated outside the body for more than a year nothing of the sort has occurred. As the bacilli always form the same masses in the internal organs, whether one examines fatal cases of typhoid fever in Russia, Germany, Switzerland, or England, so in the same way, cultivated outside the body on the same nutrient matter, they have hitherto always displayed the same manner of growth and the same mode of spore development, whether I obtained the cultivations from typhoid organs in Berlin or from the Wittenberg epidemic."

M. A. Rodet and M. G. Roux (of Lyons) consider that there are intimate relations between the bacillus coli and Eberth's bacillus; that the latter is, in fact, the former "in a state of attenuation or degeneration"; they "think that the bacillus coli becomes virulent, *typhigenic*, without notably changing botanical characters; and that it is within the organism notably in the spleen that it takes the type of the bacillus of Eberth, degenerating no doubt under the destructive acts of the organism." And they add: "It is not necessary to insist on the consequences which these facts entail relative to prophylaxis, it is not only typhoid fever dejections, but fæcal pollution of any kind which may engender typhoid fever."[3] This would have delighted Murchison's heart but it is a view which has not been generally accepted.

For a detailed description of the characters and methods of isolating and cultivating the typhoid bacillus I only need refer you to Dr. P. Horton-Smith's excellent Goulstonian Lectures,[4] delivered in this College in 1900, but I wish to refer more particularly to a specially interesting account given in those lectures of the persistence of the typhoid bacillus in the body, especially in the bile or the bone-marrow, where it has been now shown it may remain for years. Dr. Horton Smith quotes some cases from a paper by Hunner in the *Johns Hopkins Hospital Bulletin* for August and September, 1899, as follows: "In one case the bacilli were found in pure culture in the inflamed gall-bladder three months after the fever, in another eight months, and in a third after an interval of seven years." The most remarkable case of all, however, and one very carefully tested, is that recorded by von Dungern (*Münchener Medicinische Wochenschrift*, 1897, p. 699) in which 14½ years after the attack of typhoid fever the bacilli were still present in pure culture in the pus, and Dr. Horton-Smith very well adds: "Truly no longer can we say with Dr. Budd, that 'by destroying the infectious power of the intestinal discharges the disease may be in time finally extinguished.' So far, indeed, from the stools being the only agents by means of which the disease is spread they are but one of a series of agents. So far, too, from the patient ceasing to be a source of danger after his restoration to seeming health, he may carry about in himself the seeds of infection for months and even years."

A useful account of the tests used for discriminating between bacillus coli and bacillus typhosus was given by Dr. A. C. Houston in introducing a discussion on Typhoid Fever in its Public Health Aspects at the Cheltenham meeting of the British Medical Association and will be found in the *British Medical Journal* of August 17th, 1901.

Dr. Klein made an investigation on the Eberth-Gaffky bacillus which is described in the report of the Local Government Board for 1892–93. He could not find the bacillus in the blood of the living typhoid fever patient but in certain tissues of the bodies of those who had died from the disease he never failed to find it, especially in the mesenteric glands and in the spleen, and he describes its differences from the bacillus coli. The next year he reported that he had made experiments with this bacillus on monkeys. Two monkeys to whose food had been added a culture of the typhoid bacillus did not suffer in any way; no pathological lesions were found in them after they were killed, neither could the typhoid bacillus be detected in their blood or spleen. On the other hand, eight monkeys having been inoculated with cultures of the bacillus the true typhoid bacillus was found in abundance in the spleen of one of them, the bacillus coli in that of another, and "a nondescript bacillus exhibiting characters pertaining some of them to bacillus coli, others to the typhoid bacillus" was found in a third. In inoculated calves the juice of the enlarged inguinal glands was always found to contain the typhoid bacillus in abundance. The next year Dr. Klein demonstrated that under certain conditions the typhoid bacillus readily multiplies in sewage, "while as regards drinking-water he shows not only that in many different waters this bacillus may persist longer than has hitherto been demonstrated, but also that in certain of them which are to be thought of as affording pabulum for the microbe the typhoid bacillus is able on occasion to proliferate in abundant fashion."

[4] THE LANCET, March 24th (p. 821), and 31st (p. 910), and April 14th (p. 1050), 1900.

Dr. Edmund Cautley made a research on the behaviour of the typhoid bacillus in milk and his account of it will be found in the report of the medical officer of the Local Government Board for 1896–97. He found that in unsterilised milk to which the typhoid bacillus was added it was recovered in considerable numbers from the milk which had been kept for six or seven days and had turned completely sour; and in sterilised milk to which the typhoid bacillus and some other microbes were added he found that the typhoid bacillus will live in the presence of the bacillus lactis for a week but will not actually multiply under these conditions. He says "that the presence of the oidium lactis in sterilised milk does not interfere with the growth and multiplication of the typhoid bacillus" and that yeast did not interfere with the growth of the typhoid bacillus, as "both micro-organisms increased in number and neither appeared to be modified in its growth by the presence of the other." He considers that "the typhoid bacillus will live in milk under conditions which ordinarily prevail in a household. When this bacillus has been artificially added in large amount to milk in the condition in which it commonly reaches the consumer the presence of the microbes *in the living state* may be demonstrated after the milk thus treated has been kept for several days." There is no indication from the above investigations that this microbe is capable of multiplication *under the conditions in question*. Judging from the results obtained it is very probable that the number present rapidly diminishes in milk which is kept. The observations with regard to the bacillus lactis and to sour milk "indicate that it is quite possible for the typhoid bacillus to exist in curd-cheeses."

In a report by Dr. Klein on the behaviour of certain pathogenic microbes in milk, cream, and cheese he says: "It is well known that the typhoid bacillus grows luxuriantly in milk both at 20° C. and at 37° C. It does not alter the fluid character of the milk, although it produces acid, as is well known by the reddening produced when litmus milk is used as the culture medium." His experiments on cream showed "that cream kept at as high a temperature as 37° C. is not a suitable medium for the growth and multiplication of the typhoid bacillus, but that it is a suitable medium when kept at 20° C. He further found that the typhoid bacillus does not grow and multiply when planted on Cheddar cheese either at 37° C or at 20° C. (Twenty-ninth report of the medical officer of the Local Government Board for 1899–1900).

In the *Archives de Médecine Expérimentale et d'Anatomie Pathologique*, No. 1, Jan. 7th, 1889, is an account of a research made by M. J. Grancher and M. E. Deschamps on the behaviour of the typhoid bacillus in the soil. Their conclusions are as follows: "1. It does not pass through soil with irrigation water. 2. It is stopped by from 20–40 centimetres of thickness of soil. 3 It retains its life in the midst of all the organisms soil contains, five and a half months after it has been sown. 4 It does not penetrate into healthy vegetables." (*Public Health*, vol. ii., 1889-90)

A most interesting series of investigations has been made by Dr. Sidney H. C. Martin on the Growth of the Typhoid *Bacillus in Soil* and his accounts of them will be found in the reports of the medical officer of the Local Government Board for 1896–97 and onwards. He first found that the bacillus when planted in organically polluted soil, "as, for instance, the samples of earth from Chichester," speedily increased and spread abroad, whereas in an unpolluted soil from an uninhabited and cultivated area "it languished and quickly died out" under like conditions of temperature and moisture. It was then determined to test in unsterilised soil of both classes the ability of the typhoid bacillus to contend with the other microbes already present in such soil and Dr Houston was associated with Dr. Martin in this investigation. 21 samples of various soils were examined. In eight of these no bacillus coli was found. In the remaining 13 bacilli with more or less resemblance to the true bacillus coli were found and in four of these the typical bacillus coli itself was present; these four soils, however, were shown to have been polluted with excrement; while the spores of bacillus enteritidis were found in five of the soils and in exceptionally large quantity in two of them which were shown to have been polluted with excrement. Dr. Martin then showed that when the typhoid bacillus was inoculated on a soil containing bacteria belonging to the bacillus coli group it was recoverable after 50 days from this soil at the point at which it had been inoculated. "It had survived in competition with the bacillus coli-like micro-organisms but had not multiplied."

One of Dr. Martin's most important conclusions is "that the soils which are favourable to the growth of the typhoid bacillus are those which have been cultivated, more particularly soils of gardens and the *entourage* of houses. In these soils the bacillus was found to be alive and to have retained its vegetative properties for as long as 456 days; this being found true for sterilised soil which was moistened throughout with water. On drying this soil, even when it had become so dry that it could be made into a fine powder, the typhoid bacillus could still be obtained from it and had retained its vegetative properties, although it grew more slowly than when obtained from the same soil in its moist condition." Again, "In favourable soils in a moist condition the bacillus not only grew at a temperature of 37° C., but it flourished when the soil was exposed to much lower temperatures; for example, the temperature of the laboratory, which varied between 9° and 24° C. and the temperature of an outside shed between 3° and 16° C." On the other hand, virgin soils, sandy or peaty, "are absolutely inimical to the growth of the typhoid bacillus."

Dr. Martin's further investigations were made on natural "unsterilised soils which in the sterilised condition were found favourable to the growth of the bacillus. In not a single instance, however, was the typhoid bacillus regained, *although laborious and prolonged experiments were made* with this object. The obvious conclusion, therefore, was that under the conditions of the experiments the presence of the bacteria of the soil had either prevented the *detection of* the bacillus or had inhibited its growth and so led to its ultimate death and disappearance. It must be remembered that the typhoid bacillus does not form spores, so that its continued vitality depends on its power of multiplication and division. There is no resting-stage of this micro-organism as far as is known, and although in sterilised soil the bacillus will retain its viability for a while if the soil be dried at a low temperature to a powder, yet soon afterwards it dies and can never be re-vivified. Placed, therefore, amidst other bacteria under certain conditions of moisture and temperature the bacillus may in unsterilised soils be beaten out of the field by the other bacteria present." Dr. Martin's further experiments brought him to the conclusion that "there is some evidence to show that under the conditions of experiments the disappearance of the bacillus has taken place *pari passu* with an increase in the number of the putrefactive bacteria." In these experiments Dr. Martin has adopted a method of isolating the typhoid bacillus from the other bacilli present in the soil which appears to give more satisfactory results than the methods which have been previously adopted.

In a long and elaborate paper by Dr. Justyn Karlinski, published in the *Archiv für Hygiene*, Band xiii., Heft iii., the author details a number of careful experiments on the behaviour of the typhoid bacillus in earth and he draws the following conclusions.—"1. The longest life-duration of the typhoid bacillus in earth did not exceed in his experiments three months. 2. The life duration of the bacillus buried with typhoid excreta and hence under natural conditions is essentially shorter than bacilli in the blood buried in earth at the same time. 3. In the deeper layers of the earth the typhoid bacilli bid defiance to moisture, to alternations of temperature, and to the activity of other micro-organisms. 4. Exposed to moisture and sunshine on the surface of the ground the bacilli quickly die. 5. Alternating and copious moisture, whether the moisture rises into or falls on to infected earth, essentially shortens the life duration. 6. In layers of earth in which there are the active roots of plants the life duration is very short. 7. The typhoid bacilli may be recognised three months after death in certain conditions of delayed putrefaction and when the specific micro-organisms of putrefaction are denied access." (*Journal of Public Health*, vol. iv., 1891-92.)

Dr. Klein made some experiments, the results of which will be found in the report of the medical officer of the Local Government Board for 1898-99, on the Fate of Pathogenic and other Infective Microbes in the Dead Animal Body. He was unable to find the bacillus typhosus, or the bacillus coli, or the proteus vulgaris or any other aerobic microbe in the bodies of guinea-pigs which had been previously inoculated with those bacilli, buried, and exhumed 30 days or more later. His experiments showed "that the typhoid bacillus is even less resistant than the cholera vibrio. In 20 days after burial, no matter in what form this had taken place, typhoid bacilli could not be recovered from any of the bodies; from a guinea-pig buried in sand they could not be recovered after 14 days." "The German Commission exhumed the animals not earlier than one month after burial, and their examinations of the dead bodies for typhoid bacilli were in all cases negative."

In the *Journal of the Pasteur Institute* for February, 1897, is a paper by M. P. Remlinger and M. G. Schneider of the Val-de-Grâce laboratory on the Ubiquity of the Typhoid Bacillus. The authors attempt to answer the question, "Does the bacillus of typhoid exist in nature outside the sick man and the products which emanate from him?" A series of experiments extending over many months was carried out on various materials, such as the public water-supplies and wells of several towns having epidemics of typhoid, the soil and dust from different localities, the discharges from the digestive tract of persons not affected with typhoid, &c., and a bacillus giving all the principal laboratory reactions of that of typhoid was obtained from all these sources. The following illustrations are of special interest. In 13 samples of soil and dust the bacillus typhosus was found seven times, (*a*) in the refuse from barracks where there were some cases of typhoid; (*b*) in dust from the laboratory floor; (*c*) in the space between the joists of a room in other barracks; (*d*) in four specimens of soil, both superficial and a metre in depth, from the courts and gardens of Val-de-Grâce. These in three instances were pathogenic for animals. In the examination of the fæces of 10 persons treated at the hospital for affections which had nothing in common with typhoid, five reacted like the bacillus typhosus. Thus (*a*) in a case of leukæmia specimens examined at intervals of 15 days gave each time a positive result, (*b*) in one case of acute tuberculosis without intestinal lesions; (*c*) in a case of premonitory dysentery; (*d*) in two cases of chronic malaria. None of these patients had ever had typhoid fever. Of the bacilli from these five cases four were pathogenic for guinea-pigs. In many additional cultures from water, soil, and the intestines, bacilli with every characteristic of bacillus typhosus were found, except that they were not pathogenic for animals and were not agglutinated by the serum from a typhoid patient. In other words they seemed the same species but attenuated as to virulence. After some remarks illustrated by comparisons with the variations of the cholera vibrio, these investigators state: "It is allowable to suppose that facts of a similar kind reproduce themselves in connexion with the bacillus typhosus. The species of the bacillus of Eberth comprehends, perhaps, varieties more or less numerous which do not probably react similarly under the influence of the serum of an animal immunised against a determined variety. The belief in the invariability of type in pathogenic microbes is to-day much weakened by many facts. The question of race, descendants from a common stock but altered by unknown vicissitudes, acquires an importance which must not be underrated. Why should not this theory apply to the bacillus typhosus? We incline to think that bacilli not pathogenic and indifferent to the serum test which are encountered in water, soil, &c., are only varieties of the bacillus typhosus; at least, the parentage is evident even if the identity is not absolute. This diversity of fundamental type will perhaps serve to explain the variable forms of typhoid infection which are becoming recognised. If this interpretation of facts is exact the following conclusion will result. The bacillus typhosus is distributed in nature outside the human body; it is found in potable waters, in soil, in the intestines of persons not attacked with typhoid, and without doubt forms a part of the microbic flora of the media which surrounds us. This idea is not subversive of recognised facts as to the general etiology of typhoid, but rather enables us to conceive and comprehend facts otherwise inexplicable. Daily observations, especially noted in rural places, have set in relief the part played by contagion in the formation and extension of certain epidemic centres; their value remains. Modern researches have demonstrated the prime importance of impure waters in its development and spread; the character of the proof defies all question. But all the cases must originate from contagion or water polluted with the dejections of typhoid patients. Many times it breaks out in patients or groups worn out with fatigue, overwork, or privations, or after eating various foods, without its being possible to trace the origin of the contagion or the use of a badly polluted water. The facts conform more easily with the idea of the widespread presence of the bacillus typhosus, which accounts for its dispersion in surrounding media and its presence eventually in our natural cavities. A water reputed pure may carry it. Thus introduced into the organism it will live there unoffensive till some depressing circumstance, a fortuitous assistance, perhaps the result of some associated microbe, will open to it a career of action."

Dr. John Robertson, the medical officer of health of Sheffield, made a number of experiments with soil "out-of-doors." The results of these experiments "prove that the typhoid organism is capable of growing very rapidly in certain soils and that apparently under certain conditions the organisms can survive from one summer to another. The rains of spring and autumn or the frost and snows of winter do not kill them off. Sunlight has a most powerful bactericidal influence on the typhoid organism." But this action is limited strictly to the organisms actually on the surface, a layer of soil one-sixteenth of an inch in thickness protecting them. "Cultures of the typhoid organism planted at a depth of 18 inches grew to the surface; so also patches inoculated on the surface showed that at least the organism could grow downwards to a depth of three inches." (*British Medical Journal*, Jan. 8th, 1898.)

According to Liebermeister "the curves representing the frequency of typhoid correspond to the curves of average temperature, only with this difference—the different points of the typhoid curve follow those of the temperature curve by an interval of some months," and he suggests that it takes two or three months for the changes of temperature to penetrate to the breeding places of the typhoid germs. (*Ziemssen's Cyclopædia*, vol. i., p. 65.)

The present war in South Africa has lent additional interest to the question of typhoid fever in armies and the ways in which it spreads under the circumstances of camp life. In an article on Typhoid Fever in Armies in the Field, by Surgeon-Major Vincent, professor agrégé at Val-de-Grace, Paris, he states that "the predisposing causes were the average age of the soldier; the time of year chosen for military operations, summer or autumn; imperfect feeding and the digestive troubles which resulted therefrom; the inevitable deficiencies as to hygienic conditions as regards both the soldier's body and his clothes; a hot climate, as is the case in colonial wars; the shutting up of troops in camps or besieged towns; a very prolonged war and the demoralisation of an army when conquered. The immediate cause was the ubiquitous bacillus typhosus. This bacillus was able to live in a latent condition in the digestive tract and thence under favourable conditions to multiply itself and give rise to the appearance of a spontaneous epidemic." (THE LANCET, August 11th, 1900, p. 437.)

Some information on the matter is to be derived from the report of Dr. G. Pratt Yule on the camps in the Orange River Colony, published in the *Times* of Dec. 16th, 1900, the most important sentence in which from our point of view is the following. After referring to the fouling of the ground round the tent doors by urine and slops, he says: "Practices such as these have undoubtedly proved the source of a large proportion of the typhoid cases, and these will certainly greatly increase during the coming summer and autumn. In this particular it is important to remember that urine of convalescent typhoid fever patients often contains a pure culture of the typhoid germ which by methods of disposal like the above becomes blown about in the dust of the camps. I am of opinion that the typhoid infection of the camps is principally air-borne."

In the *British Medical Journal* of Nov. 10th, 1900, is an article on an outbreak of typhoid fever at Quetta, India. At this place the water-supply is derived from the hills and is above suspicion. There was, as usual, freedom from typhoid fever up to May but from May 2nd to 13th there were dust-*storms with sore throat and tonsillitis, followed by an outbreak* of typhoid fever, some of the cases commencing with *sore-throats. The night-soil was placed in pits to the north-*west, from which the prevailing wind blew, and in the dry air the deposited matters were dried and blown about as dust. Those companies suffered most who were nearest to the filth-pits; the air from the quarter where the filth-pits were contained "large numbers of germs that are invariably present in fæcal matter and not in pure air, although the enteric bacillus itself was not isolated." It appears from a subsequent article on Sept. 14th, 1901, that "the outbreak ceased on removal of this source of infection." It is also stated that in Jhansi, Nasirabad, Mhow, and Rawal Pindi typhoid fever prevails during the dry season and the dust-storms, and that, on the other hand, Roorkee has very little typhoid fever and is comparatively free from dust.

Dr. H. E. Leigh Canney has published an interesting paper on Typhoid, the Destroyer of Armies, and its Abolition. He holds the view that nearly all the cases of the disease on service are water-borne and in order to prevent it he propounds a scheme for boiling the whole of the water used and suggests the formation of a Royal Water Corps to be devoted to the work of supplying sterilised water, boiling the milk, and "the disinfection of all salads after they have been washed in ordinary water," the watchword of the water corps on a campaign to be "boiled water or nothing" These suggestions met with considerable support at the meeting of the Royal United Service Institution, where the paper was read. Sir William Broadbent, the chairman, pointed out that "whatever importance might attach to dust and flies they were subsidiary to the infection by water. With regard to the efficiency of the method proposed by Dr Canney, Sir William Broadbent thought that if it could be secured that no soldier drank anything but boiled water they would get the upper hand entirely of typhoid The whole question turned upon the practicability of the scheme which had been well thought out and was not brought forward in a nebulous condition. Although, of course, they must bear in mind that after a long march or after the excitement and exertions of a fight a soldier could not be prevented from drinking the first water he came across, yet if he started with his bottle full of pure water and the water-carts contained nothing but pure water, whilst only pure water was drunk in the camps, an enormous gain would have been secured." Major R H Firth, the professor of military hygiene at Netley, expressed great sympathy with the proposed scheme. He considered that sanitary officers should undergo a special training and they must be supplied with properly instructed men to carry out the work. Dr. J. W. Washbourn insisted that the disease was also conveyed by flies and dust and thought that it was not difficult to provide for a proper disposal of excreta and so to prevent much of the distribution of the poison of the disease by the agencies just mentioned

A discussion on the Recent Epidemic of Typhoid Fever in South Africa was opened at the Clinical Society of London by Dr. Howard H. Tooth and reported in THE LANCET of March 16th, 1901, pp. 771, 786. He is of opinion that the disease is spread in South Africa not merely by polluted water but also by dust and flies, and he says of the flies that "they naturally infest persons who are ill but seem to be peculiarly attracted to enteric fever patients, hanging in loathsome groups around their mouths and feeding-vessels. They were all over our food, and the roofs of our tents were at times black with them. It is not unreasonable to look upon flies as a very possible agency in spreading the disease not only abroad but at home." He also points out "that with the first appearance of the frost enteric fever almost entirely disappears .. . it seems *hardly credible that the almost* sudden cessation of an epidemic can be due to the effect of cold upon the enteric fever bacilli only. But there can be no doubt in the mind of anybody who has been living on the open veldt as we have for three or four months that the flies are extremely sensitive to the change of temperature and *that the cold nights kill them off* rapidly. On consideration of these points it is surely justifiable to assign an important share to flies in the spreading of infection."

In the *British Medical Journal* of Feb. 15th, 1902, is a paper by Lieutenant-Colonel R. H. Quill, R.A.M.C., senior medical officer, Ceylon, on Air-borne Typhoid Fever. He maintains that the disease is frequently air-borne and gives *his experience of it at the camp of Diyatalawa* in the hills of Ceylon, which was formed in August, 1900, for the Boer prisoners of war There occurred at this camp an outbreak of typhoid fever which was certainly not due to the water *or milk*, the water-supply and filtration arrangements having been changed in no way since the cessation of the epidemic *among* the prisoners, and there have been no cases of typhoid fever since 1900 No uncooked food or vegetables were used in the camp. All men leaving the camp for purposes of duty or pleasure were obliged to take with them a water-bottle filled with filtered water. The aerated waters used in the camp were identical with those used at the sanatorium where there was no typhoid fever Lieutenant-Colonel Quill was driven to the conclusion that the affection was air-borne, being derived from the adjoining camp for prisoners of war, where at the time an epidemic of typhoid fever was raging. After giving his reasons for that opinion he submits that he has shown (1) that all water avenues through which typhoid fever could have been conveyed to the military camp at Diyatalawa were efficiently guarded and that therefore a water-borne origin must be abandoned; and (2) that the affection was air-borne, resulting from emanations from specifically infected latrines, infected dust, or bacilli-laden flies.

Dr. A. Elliot and Dr. Washbourn contributed a paper on Typhoid Fever in South Africa to THE LANCET of Jan. 18th, 1902, p. 139. They conclude "that the type of typhoid fever met with in South Africa does not differ in any essential respects from that met with in England and America. The mortality and the incidence of complications are much the same as in the variations which are met with elsewhere; the only complication which appears to be especially prominent is phlebitis which occurred in 5 6 per cent. of our cases. .... We do not feel that inoculation has any marked influence either in preventing or in modifying the disease."

Since then Dr. George Turner, the medical officer of health of the Transvaal, has contributed a paper to the *British Medical Journal* of Feb. 15th, 1902, on Typhoid Fever in South Africa, its Cause and Prevention. In it he states that he should not advance his opinion on the matter if he "did not feel that the growing tendency to attribute enteric to wind and flies was not becoming a source of danger." He maintains from six years' experience "that the causation of epidemics in South Africa is practically similar to that which gives rise to the majority of cases in England—viz., a polluted water supply" He states that only on one occasion has he "had any grounds for supposing that dust was concerned in the production of typhoid and on that occasion the dust appeared to have acted through the agency of the water used for drinking" He does not deny absolutely the possibility of typhoid infection by means of wind-borne dust but he says that it is rare. "As a matter of fact, typhoid cases are less frequently met with just at the period at which *dust-storms* prevail and are more numerous when, on account of heavy rain, dust is less troublesome. This, to my mind, is conclusive proof that dust does not exert much *injurious* influence as regards typhoid. As regards flies I can only say that I hold a similar opinion. The possibility of the conveyance of enteric through these pests is undeniable, but in this instance *also* the *supposed cause, the* flies, begin to be troublesome long before typhoid prevails and continue to annoy us long after it has subsided. If the flies were really important agents in the spread of typhoid fever one would expect that even if the disease did not commence to prevail soon after these nuisances commenced to be numerous, .. . *because it is conceivable that* at the time typhoid-infected stools would be rare, yet when once typhoid became common the flies should carry on the infection which should continue as long as, or longer than, the flies continue." Finally, he strongly maintains that "typhoid in South Africa is almost entirely due to polluted water" He *admits that filters were* sent out with the troops but states that they were not generally used; while, on the other hand, "where the commanding officer had a 'fad about water' the case incidence of typhoid was insignificant." To show that he does not underrate the difficulty of supplying an army with water when on the march he adds: "My private opinion is that if the army had been supplied with the best sanitary expert advice on the march from Paardeberg to Bloemfontein one of two things would have resulted, either the army would never have reached Bloemfontein or it would, as it did, have suffered from fever; one or other of these results was inevitable." The report of the Commission sent to South Africa, consisting of Professor J. Lane Notter, Professor W. J. R. Simpson, and Lieutenant-Colonel Bruce, has not yet been published, so that unfortunately I cannot avail myself of the information contained in it for the purpose of this lecture. I have, however, Professor J. Notter's permission to state as his own personal opinion that he considers "that while water was a very frequent cause of typhoid fever among the troops it could not, I think, be said to be the *only* cause of it. Others were the aggregation of men on limited areas—density of population—without any of the usual methods of drainage and the disposal of excreta and refuse which exist where numbers are usually congregated together in towns and villages in civil life; this state of things is always present in standing camps; the transference, too, of the contagion by flies, which constitute a real danger unless food is properly stored and kept from them, especially where trench latrines are used. The soil, too, is an important factor; the ground seems wanting in nitrifying organisms, the result being that animal refuse remains long without undergoing that process of disintegration and oxidation that is usual in this country. Perhaps this is due to the absence of lime or like base, for lime is seldom found in large tracts of the Orange River Colony and Transvaal."

I originally intended the subject of these lectures to be merely the "Etiology of Typhoid Fever" and this would have been quite sufficient, but I afterwards thought that it would add to their interest if I showed how the mortality from this disease has been diminished in this and in some other countries by suitable methods of prevention. The methods of prevention themselves are those which apply to any infectious disease and have been described so frequently that there is no need for any further account of them, the only peculiarity in the case of typhoid fever being that less attention need, as a rule, be paid to the methods of preventing direct infection, whilst the greatest attention should be given to the prevention of indirect infection by the channels which have been already described in these lectures. As the disease is no doubt chiefly conveyed by drinking-water it is of the highest importance that this water should not be contaminated with the typhoid poison, or, as Sir John Simon puts it, "It ought to be an absolute condition for a public water-supply that it should be uncontaminable by drainage." Suitable precautions, too, must be taken to prevent other foods, such as milk, oysters, &c., from becoming contaminated. The soil under houses and the air in and around them must be kept pure by the adoption of methods for the removal of excreta from the vicinity of habitations speedily and continuously. The late Sir George Buchanan showed us that the death-rate from typhoid fever was especially lowered in towns where refuse matters were removed most quickly. Among these methods for the prevention of the contamination of the soil and the air are the provision of water-tight house drains, their disconnexion from the public sewers or cesspools, their proper ventilation, and the provision of sanitary appliances and pipes which insure the speedy removal of the foul matters from the houses and prevent the escape into them of any foul air from the drains or sewers. All these matters have been so thoroughly discussed by me in other public lectures that it is quite unnecessary for me further to enlarge on them here.

There appear to be differences of opinion with regard to the disinfection of typhoid excreta; some advocate mixing them with sawdust or other absorbent material and burning them, whilst others are in favour of boiling them. On this subject I may quote Lieutenant-Colonel G. H. Younge, R.A.M.C., who wrote in the *British Medical Journal* of Jan. 18th, 1902: "When in India I tried the process of incineration of enteric excretions mixed with sawdust, but the attempt had to be discontinued as it was found impossible completely to burn the wet sawdust in any incinerator that could be extemporised. On the whole, therefore, I have a decided preference for sterilisation by boiling, as it is quite as effective, less expensive, and more rapid and convenient than incineration." This seems to me to be unanswerable and it is, in fact, obvious that the simplest and quickest way to disinfect liquid excreta must be to boil them.

In a remarkable report on the Results which have hitherto been gained in Various Parts of England by Works and Regulations designed to promote the Public Health Sir George Buchanan said: "Many of the public improvements have coincided with reduction of typhoid. Though not with absolute constancy, drying of the soil of a town and reduction in the crowding of houses have been followed by reduction of fever. Much more important appears to be the substitution of an ample supply of good water for a scanty and impure supply; other things being equal the towns in which this substitution has been completed have made most improvement. Merthyr is a conspicuous instance of a town where before any other important change had been made typhoid fell to a notable extent as soon as inspection and cleansing were adopted. It is, however, the purification of atmosphere from decomposing organic matters that has been most uniformly followed by a fall in the prevalence of typhoid. And this has occurred equally whether the purification has been brought about by the abolition of cesspools or by draining and drying 'middens.' Apparent exceptions, indeed, are found in certain towns (viz., Rugby, Carlisle, Chelmsford, and Worthing). But in these four towns and in no others sewage is received into pumping works at the outfall in such a way that sewer gases are necessarily much confined in the pipes. In the case of Worthing the defect of the outfall arrangement was most serious and in the absence of other exits sewer gases had demonstrably been forced into houses and outbreaks of typhoid had occurred as the demonstrable result thereof. In the other towns, though to an inferior degree, there were facilities for the same accident occurring. So that it appears that the four towns where fever has not been greatly reduced are so far from constituting an exception to the rule—that removal of organic impurity from the air has been followed by reduction of typhoid—that they even add strongly to the presumption that the rule is absolute and universal." (Ninth report of the medical officer of the Privy Council, 1866.)

In May, 1899, Dr. Saltet, professor of hygiene in the University of Amsterdam, read an important paper before the Epidemiological Society on a Study of Enteric Fever in the Netherlands during the period 1875 to 1894. He stated that "during the last decade the number of deaths from typhoid fever has been, generally speaking, on the decrease" and this to a greater extent than the decline in the general death-rate, for while he shows that the general death-rate in the Netherlands declined in the period under review from 23·3 per 1000 living during the quinquennium 1875 to 1879 to 20·0 during the quinquennium 1890–94, or an improvement of 14 per cent., that from continued fevers has declined from 60 per 100,000 to 22, or an improvement of 63 per cent., thus showing "that typhoid fever as a preventable disease *par excellence* has yielded more favourably to the improved condition of the times than other diseases." He then discusses the influence of density of population and comes to the conclusion that "the favourable factors of town life appear thus to outweigh the unfavourable conditions due to density of population." With regard to drinking-water he arrives at the interesting and unexpected conclusion that the death-rate from continued fevers is higher in communes supplied with water from the sandhills than in those with a river-supply, although it has decreased considerably in both; thus in those with the water-supply from the sandhills the death-rate from continued fevers was 60 per 100,000 in the first quinquennium and fell to 19 in the fourth quinquennium, whereas that in communes with the river-supply was 32 in the first quinquennium and fell to 15 in the fourth. Professor Saltet's explanation of this anomalous state of affairs is that "in communes on rivers a sufficient quantity of fresh water is always to be obtained independent of water systems. A number of communes with the ground-water system were, however, frequently suffering from a want of water. Now want of water means want of cleanliness, and it is not at all unlikely that *and* a better quality *and* a more adequate quantity of the drinking-water supply as well as the more liberal use of it have greatly assisted in bringing down the death-rate from fevers. The striking fact remains, however, that in communes with the ground-water system the death-rate from general causes is lower, whilst the mortality due from continued fevers is higher than in the river-water communes. This phenomenon impresses us even more forcibly if we consider that Asiatic cholera, a disease especially propagated by drinking-water, has in the Netherlands played the greatest havoc along the course of the rivers." This would make it seem probable that the increased amount of typhoid fever in communes with a water-supply from the sandhills was due to some other cause than the water, or else that the sources of water-supply are liable to surface contamination.

The hitherto published results of anti-typhoid inoculation are so contradictory and, moreover, are based on such small numbers of cases that I do not think any good end would be attained by further alluding to them

In preparing Tables III. to VI. I have been able to include the statistics for 1900 and so to make the tables complete to the end of the last century, owing to the courtesy of my friend Dr J F W Tatham, chief of the Statistical Department of the General Register Office. Table III shows the remarkable diminution in the general death rate of London during the last half of the last century It will be seen from it that the average general death rate from 1851 to 1870 was 24 1 per 1000 per annum and that it had gone down to 18 8 in the quinquennium 1896 to 1900, the dates at which the important Acts relating to the public health were passed are shown in the table.

TABLE III —*London*

Years	Average death rates per 1000 per annum.
1851-1870	24 1
Nuisance Removal Act 1855, Sanitary Act, 1866.	
1871-1890	22 5
Public Health Act London 1891	
1891-1895	20·2
1896-1900	18·8

In Table IV the corresponding figures are shown with regard to the general death rate in England and Wales. The average from 1849 to 1875 was 22·4 per 1000 per annum. The Public Health Act was passed in 1875 and after that the table shows a steady diminution of the death rate until in the quinquennium 1896 to 1900 it was only 17·6.

TABLE IV —*England and Wales*

Years	Average death rates per 1000 per annum
1849-1875	22·4
Public Health Act 1875	
1876-1880 ..	20·8
1881-1885	19·4
1886-1890 ..	18·9
1891-1895	18·7
1896-1900	17·6

Dr Bulstrode prepared a most interesting chart and maps showing the annual death rate from typhoid and continued fevers per 100 000 living in the counties of England and in North and South Wales during each of the decades 1871–80 and 1881–90 They show "that whilst enteric fever has been undergoing enormous diminution in this country, the areas of both its maximum and minimum incidence have remained practically the same during the 20 years 1871 to 1890, which have witnessed such great improvements in the sanitary circumstances of our towns and villages. The chart shows, amongst other things, that whereas this (typhoid and continued) fever death rate in England and Wales was 43 per 100,000 living during the decennium 1871 to 1880 it had fallen to nearly half—viz., 22 per 100,000—during the decennium 1881 to 1890 ' (Sir R. Thorne, twenty-sixth report of the medical officer of the Local Government Board, 1896–97)

TABLE V —*Average Annual Death rates from continued Fevers and Diarrhœa per 1 000,000 Persons living in England and Wales*

Years	Continued fevers (chiefly typhoid).	Diarrhœa.
1861-70	885	1076
1871-80	482	936
1881-90	235	674
1891 95	185	630
1896-1900	180	788

TABLE VI —*Average Annual Rates of Mortality from Typhoid Fever per 1,000 000 Persons living in each Quinquennium from 1871 to 1900*

—	1871-75	1876-80	1881-85.	1886-90.	1891 95.	1896-1900.
In England and Wales	354	278	218	180	178	178
London	256	234	226	150	136	148

Table V shows that the rate of mortality in England and Wales for continued fevers (chiefly typhoid) has been reduced from 885 per 1 000,000 persons in 1861–70 to 180 in 1896–1900 and for diarrhœa from 1076 in 1861–70 to 630 in 1891–95, but that the latter rose again to 788 in 1896–1900, and Table VI. shows the steady diminution of the death rate from typhoid fever alone during each quinquennium from 1871 to 1895 both in England and Wales and in London. It will be noticed that during the last quinquennium (1896–1900) the death rate from this disease was the same in England and Wales as in the previous quinquennium (1891–95) thus showing no diminution while in London there was actually an increase in 1896–1900, when the average rate was 148 per *1,000,000 persons over that in 1891–95, when it was 136.* This, as well as the increase in the diarrhœa rate, was due to an unusual prevalence of both these diseases in the years 1899 and 1900

I have already referred to the remarkable diminution of the death rate from typhoid fever at Munich owing to the improvements carried out under the advice of the late Professor Pettenkofer, a diminution which is even far more remarkable than the diminution in London and in this country generally

From a paper on the Diminution of Typhoid Fever in Paris published in the *Revue Municipale* of Dec. 29th, 1900 I find that the death rate from that disease per 1,000 000 persons living has diminished in a very notable manner, as shown by the following figures. In 1882 it was 1430, from 1883 to 1888 it was 581, from 1889 to 1894 it was 293, and from 1895 to 1900 it was 172. And this in spite of a recrudescence in 1899 and 1900, which was brought into prominent notice on account of the great Exhibition held in Paris in 1900 but which was shared by London and England generally and would not have been specially noticed had it not been for the Exhibition.

NOTE ON THE RELIEF OF A DISTENDED JOINT BY THE ESTABLISHMENT OF SUBCUTANEOUS LEAKAGE[1]

BY T PRIDGIN TEALE, M.A. OXON, F.R.C.S. ENG, F.R.S,
CONSULTING SURGEON LEEDS GENERAL INFIRMARY

THIS communication is called a 'note' because I have to speak from memory and not from recorded data. The cases which I recall occurred chiefly in my early days as surgeon to the Leeds General Infirmary, at a time when we had no very *satisfactory system of preserving for ready reference the* records of surgical cases.

CASE 1.—The first instance in which I deliberately employed this treatment was as follows. A young woman about 25 years of age was under my care on account of an acute distension of one knee attended with intense pain The conditions suggested to my mind suppuration and the question whether I ought not to open and to drain the joint. As such a proceeding was at that time more or less on its trial I held a consultation with my colleague who agreed with me that pus was almost certainly present and that I should be justified in opening and draining the joint. As a commencement I punctured the joint carefully with the narrow curved bistoury of the period and by turning it sideways I allowed some of the fluid to escape. To my dismay the fluid was not pus but slightly turbid synovial fluid. After hesitating for a minute what to do and with the fear before me which we had at that time of opening a joint that was not suppurating, I decided so to manœuvre the knife as to make an opening in the capsule about half an inch in length in order that the fluid might leak into the surrounding extra-articular tissues where it was likely to be absorbed. In order to render this process as thorough and rapid as possible I made three or four other punctures into separate regions of the synovial cavity, taking care that the openings in the skin were not larger than the width of the narrow blade, whilst the capsular openings were about half an inch in length. The result proved to be even better than I dared to hope. The pain ceased, the effusion disappeared, and the joint rapidly recovered. The idea occurred to me, no doubt, from having seen the effect of acupuncture of hydrocele in children, in which several leakage punctures allow the fluid to disappear into the cellular tissue and become absorbed. Also, I have some recollection that the older surgeons occasionally treated pleuritic effusion by acupuncture with a view to allowing the pleural fluid to leak into tissues outside the thorax and to become absorbed.

---

[1] A paper read before the Leeds and West Riding Medico-Chirurgical Society on Feb 28th, 1902.

The case I shall next refer to occurred in private practice and of this I have notes.

CASE 2.—A boy, aged nine years, who was always delicate but who suffered from no known injury, began to walk with a slight limp which increased without much pain. There was arching of the back when the right limb was straight upon the bed. On March 6th, 1891, under ether, I made a subcutaneous incision through the capsule of the right hip-joint so as to establish a leakage, and at the same time I divided the tensor vaginæ femoris and the abductor longus tendon which were tense. On the 24th the immediate result seemed to be satisfactory. The patient was out-of-doors a good deal walking about and he slept and ate well. The report on April 15th was, "Going on well," but on May 10th it was, "Not so well, more pain." On Sept. 1st the note states, "Going on favourably, able to go about but walking lame." On Jan. 15th, 1892, the patient had relapsed and an abscess was forming in the front of the hip-joint. The head and neck of the bone were therefore excised, the head being eroded. In this case there was a temporary arrest of the synovial distress but the treatment eventually failed, probably because the focus of the disease was beneath the articular surface of the femur.

My colleague and former house surgeon, Mr. W. H. Brown, tells me that he well recollects one case of mine of distended elbow-joint in which subcutaneous leakage arrested the distension of the synovial membrane. My colleague, Mr. Harry Littlewood, remembers my conversations on this subject, and says that from them he deduced his practice in reference to operations on joints. When he opens a joint with a healthy, or comparatively healthy, synovial membrane, he is careful not to close entirely by suture the synovial cavity, but he leaves a sufficient opening to allow synovial effusion to leak into surrounding tissue where it is absorbed and does not become a source of injurious distension.

Remembering that some 20 years ago Dr. James Hardie, surgeon to the Manchester Infirmary, had proposed to read a paper at the meeting in Manchester of the British Medical Association on this or a kindred subject I wrote to ask him about it. He has kindly sent me a reply which he allows me to use:—

> MY DEAR SIR,—You are quite right in thinking that I had at one time something to say about subcutaneous incision of joint capsule. I never read the paper, however, nor did I publish it. It had reference entirely, I think, to the hip. I had in several cases opened the distended capsule with a tenotome with great relief to suffering and, as I believed, with advantage as regards the progress of the case. My views as to the pathology of hip disease underwent a change about that time, however, as I came to the conclusion that in the great majority of cases it begins in the subchondral layer of bone and then affects the synovial membrane, instead of beginning in the latter. For that reason I came to regard early excision as the treatment.
>
> JAMES HARDIE.

Perhaps some apology may be due from me for bringing forward a method of treatment which is probably only applicable to a case now and then under exceptional circumstances and in support of which I have such scanty data to produce. As, however, I am convinced that there is a possible sphere in which it may prove of value I think that it is right to place my views before the profession, hoping that the suggestion may sometimes and in other hands prove fruitful.

Leeds.

A CASE OF FAT-EMBOLISM AFTER FRACTURE, WHERE FAT WAS PRESENT IN THE SPUTUM AND URINE.[1]

BY F. A. SOUTHAM, M.A., M.B. OXON., F.R.C.S. ENG.,
SURGEON TO THE MANCHESTER ROYAL INFIRMARY; PROFESSOR OF CLINICAL SURGERY, OWENS COLLEGE, MANCHESTER.

THE following account of a case of fat-embolism after fracture may prove of interest, for of recent years little attention has been directed to this subject and few cases have been recorded in this country.

A male, aged 43 years, was admitted into the Manchester Royal Infirmary on Nov. 8th, 1901, suffering from a compound fracture of the right tibia, about its middle, which was caused by direct violence, a bale of cotton having fallen across his leg a few hours previously. There was a small punctured wound at the seat of fracture, but very slight bruising, and no apparent displacement or comminution of the ends of the bone. The fracture was treated in the ordinary way, the wound being syringed with a solution of perchloride of mercury, a dry dressing being applied and the limb being put up on a back splint with a footpiece. On the following morning the patient was unusually drowsy and his friends who visited him noticed that there was a distinct impairment of his usual mental condition. In the evening he rambled slightly in his talk and made several attempts to get out of bed. His temperature was 100·4° F. On the 11th the drowsiness was more marked, so that he was with difficulty aroused. When awakened and raised in bed for the purpose of feeding he would quickly lapse into a state of somnolence, even while supported in the arms of a nurse. On several occasions he coughed up some blood-stained sputum. The temperature was 100°. On the 12th a number of minute globules were noticed by my house surgeon, Mr. H. S. Lister, floating on the surface of the urine. These were examined microscopically by Dr. W. E. Fothergill, director of the clinical laboratory, and were found to consist of fat, for when treated with osmic acid they became stained of a blackish colour; no blood-cells were noticed in the urine. The temperature was normal and afterwards remained so. On the 14th an examination of the blood-stained expectoration showed numerous fat-globules mixed with red blood-cells. Evidences of consolidation were found at the base of the right lung, an area of dulness about three inches in diameter being present. There was no dyspnœa or other signs of pulmonary obstruction. After this date the patient rapidly improved, the lung clearing and the expectoration becoming free from blood. No further evidence of fat was noticed either in the sputum or urine. The drowsiness and other mental symptoms gradually disappeared. He left the hospital at the end of a month wearing a plaster-of-Paris bandage, good union having taken place and the wound having healed without any suppuration.

Remarks.—The case is a good illustration of the condition described as fat-embolism, a complication occasionally observed in fractures, simple as well as compound, owing to absorption of broken-up fat-globules by the blood-vessels. It is believed that in consequence of the crushing or splintering of the bone the fat-globules of the medulla gain access to the venous circulation through openings in the vessels in the neighbourhood of the fracture, and these acting as emboli are carried on by the blood-stream until they become arrested in the capillaries of various tissues and organs, the organs most commonly affected being the brain, the lungs, and the kidneys.

It is probable that fat-embolism takes place more frequently than is generally supposed, the symptoms being overlooked in slight cases, and if it had not been for the careful observations of my house surgeon its presence might have not been recognised in this instance. The drowsiness and other mental symptoms which were noted for several days after the injury were undoubtedly due to interference with the cerebral circulation, owing to blocking of the capillaries of the brain by particles of fatty matter.

The presence of fat in the sputum and urine showed that the lungs and kidneys were also affected, these being the organs by means of which the fat becomes eliminated from the system when recovery takes place. In severe cases the cerebral and pulmonary circulation may become so seriously interfered with, owing to blocking of the vessels, that death results, the patient in the former case becoming comatose and in the latter suffering from dyspnœa and other signs of pulmonary obstruction. Some years ago I published in THE LANCET[2] a fatal case of compound fracture of both lower extremities where this complication was met with. A microscopical examination of the lungs after death showed extensive plugging with fatty emboli, their presence in the pulmonary capillaries being rendered evident by staining sections of the lung with osmic acid, and a figure was given showing the condition which was found.

---

[1] A paper read at a meeting of the Manchester Pathological Society on April 16th, 1902.

This case and the one above recorded are the only two instances of fat-embolism which have come under my notice where its presence has been actually verified, and it would be interesting to ascertain what is the experience of surgeons generally with reference to the frequency of this condition as a complication of fractures.

Manchester.

SOME STATISTICS REGARDING THE EFFECT OF INOCULATION AGAINST TYPHOID FEVER IN SOUTH AFRICA.

BY ALEXANDER CROMBIE, M.D. EDIN.,
BRIGADE-SURGEON-LIEUTENANT-COLONEL, I.M.S., BENGAL (RETIRED); LECTURER ON TROPICAL DISEASES AT MIDDLESEX HOSPITAL.

OF 250 officers who recently came before the Medical Board at 18, Victoria-street, London, S.W. (of which I am a member), invalided from South Africa on account of wounds and disease, I found that *112*, or *44·8* per cent., had been inoculated against enteric fever; that 29, or 11·6 per cent., had had a previous attack of typhoid fever; and that 109, or 43·6 per cent., had not been inoculated or had a previous attack. Of the total number (250) 59, or 23·6 per cent., suffered from enteric fever in South Africa, but of these a considerable number were actually invalided on account of debility following enteric fever, so that this latter percentage cannot be put forward as representing the real proportion of officers so infected. It is, of course, considerably higher than the actual ratio. Of the 112 who were inoculated 32, or 28·5 per cent., suffered from typhoid fever; of the 29 who had had a previous attack only 3, or 10·3 per cent., had a second attack in South Africa; and of the 109 not inoculated 24, or 22 per cent., had attacks in South Africa. Of the 112 who were inoculated 102 had been inoculated once, with 30 cases, or 29·4 per cent.; and 10 with two cases, or 20·0 per cent., had been inoculated twice. In tabular form these figures appear as follows:—

TABLE I.

—	Number	Cases	Per cent.
Inoculated once	102	30	29·4
„ twice	10	2	20·0
Total inoculated	112	32	28·5
Previous attacks	29	3	10·3
Not inoculated	109	24	22·0
Totals	250	59	23·6

I wish to offer as few comments on my figures as possible, but it is only fair to state that there is a very general consensus of opinion among medical officers in South Africa that inoculated cases run a milder and more favourable course than the non-inoculated do. According to the statistics of Dr. H. H. Tooth this leads to a higher percentage (2·5 per cent.) of recoveries among men, and for obvious reasons it would probably be higher among officers. If this is so a group of invalided officers would contain a higher percentage of cases among the inoculated in the proportion of the higher percentage of recoveries.

Assuming that inoculation affords a certain amount of protection against infection, as Professor Wright's statistics would seem to indicate, I have endeavoured to arrive at a conclusion as to how long that protection lasts. For that purpose I ascertained from each officer the dates of his inoculation and of his arrival in South Africa, when it is presumed that he became liable to infection, and the date of his attack of enteric fever. In all but one case the inoculation was performed on board ship on the way out—that is to say, 10 or 14 days before arrival in South Africa, and in the following tables the date of inoculation is ignored as complicating them unnecessarily, and it can be calculated from these data. The one exception was in the person of an officer who was inoculated twice before leaving England.

In the following table the first column gives the months after arrival in South Africa and the other columns the number of officers affected in each month after arrival, among the non-inoculated as well as among the inoculated, so as to obtain a basis for comparing their relative susceptibility at increasing periods after disembarkation. This table also shows the average time which elapsed between disembarkation and the attack. It shows that the average date of attack among the inoculated was 9·4 months (9·8 for those inoculated once and 6·5 for those inoculated twice) and 10·3 months among the not-inoculated. I made the calculation at several periods of the inquiry and found that it always maintained the same relation, showing obedience to some law affecting the figures.

TABLE II.—*Showing the Actuals attacked in each Month after Disembarkation in South Africa among Inoculated and Not-inoculated as well as the Average Time of Infection.*

Months.	Inoculated.			Not inoculated.
	Once	Twice.	Total	
1	—	1	1	—
2	—	—	—	2
3	7	—	7	7
4	1	1	2	2
5	3	2	5	1
6	4	—	4	2
7	3	—	3	2
8	1	—	1	—
9	5	—	5	3
10	2	—	2	1
11	2	1	3	3
12	4	—	4	2
More than a year.	14	1	15	16
Totals*	46	6	52	41
Aggregate of months ..	457	39	496	399
Average time in months ...	9·8	6·5	9·4	10·3

* These totals do not agree with those given in Table I. because this inquiry was begun before the other.

In order to see the force of these figures it is necessary to reduce them to percentages. This I have done in Table III., in which the figures given represent "progressive percentages." Thus among the 46 inoculated once there were seven cases in the third month after disembarkation, giving a percentage of 15·2. By the fifth month there had been 11 cases (including seven in the third month, one in the fourth and three in the fifth) giving a progressive percentage of 23·9. In the last column is shown the difference between the incidence of the disease among the not-inoculated and the inoculated. This column shows that the not-inoculated suffered more during the second, third, fourth, and fifth months than the inoculated did; and if those inoculated twice were excluded from the table the advantage would remain with the once inoculated up to and including the sixth month. Subsequently to that time the advantage lies with the not-inoculated, an advantage which at the end of the first year and subsequently amounts to 10 per cent.

TABLE III.—*Showing in Progressive Percentages the Numbers of Inoculated and Not-inoculated attacked by Typhoid Fever at Increasing Periods after Disembarkation.*

Months.	Inoculated.			Not inoculated.	Differences.
	Once.	Twice.	Total.		
1	—	16·6	1·9	—	− 1·9
2	—	16·6	1·9	4·9	+ 3·0
3	15·2	16·6	15·4	21·9	+ 6·5
4	17·4	33 3	19·2	26·8	+ 7·6
5	23·9	66 6	28·8	29·3	+ 0·5
6	32 5	66 6	36·5	34·1	− 2·4
7	39·1	66 6	42 3	39·0	− 3·3
8	41·3	66 6	44·2	39·0	− 5·2
9	52 2	66·6	53·8	46·3	− 7·5
10	56·5	66·6	67 6	48 8	− 8 8
11	60·9	83 3	63·5	56·1	− 7·4
12	69 5	83·3	71·1	60·9	− 10 2
More than a year.	30·5	16 6	28·9	39 1	+ 10 2
—	100	100	100	100	—

The figures regarding a second inoculation are too small to form ground for any decisive opinion as to its advisability. Table I. would seem to indicate a smaller liability to attack in the long run, while Tables II. and III. point to a greater liability on exposure to infection soon after the operation.

The following are facts of general interest. A medical officer found six months after inoculation that his blood gave a well-marked agglutinative reaction. A fortnight afterwards he was in bed suffering from enteric fever, showing, as is well known, that the presence of agglutinins is no guarantee of that of alexins. Dr. B—— was inoculated twice in February and twice in June, 1897; he was again inoculated twice in February, 1900 In October, 1900, he had an attack of enteric fever in South Africa followed by a relapse and thrombosis. In May, 1901, he had a second attack of enteric fever again followed by thrombosis. When his blood was examined in London at the end of 1901 it gave no agglutinative reaction nor had it any effect on the motility of the bacillus typhosus in six hours. In three out of four cases returned in South Africa as simple continued fever a positive Widal reaction was found.

I offer these figures as a contribution to our knowledge of the prophylactic effect of inoculation against typhoid fever pending the compilation of official statistics on a large scale which, it is hoped, will be possible after the conclusion of the war.

Bickenhall Mansions, W.

AN UNDESCRIBED URINARY DEPOSIT: MONOHYDRIC MAGNESIUM PHOSPHATE.

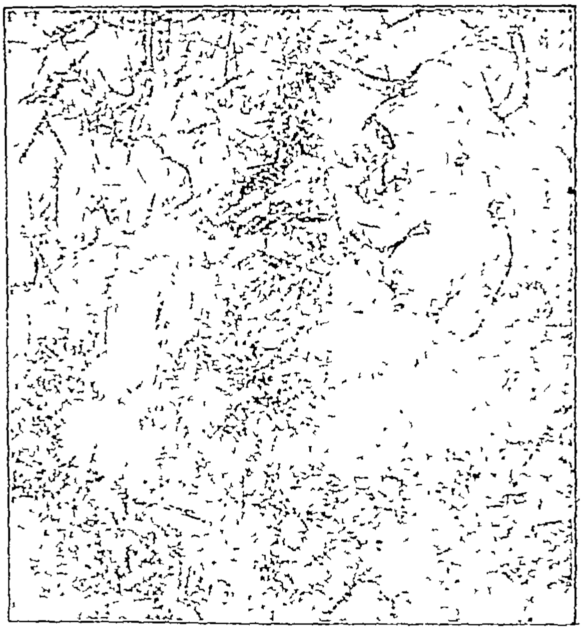
BY T. R. BRADSHAW, B.A., M.D. DUB., M.R.C.P. LOND.,

PHYSICIAN TO THE LIVERPOOL ROYAL INFIRMARY; CONSULTING PHYSICIAN TO THE SAMARITAN HOSPITAL FOR WOMEN, LIVERPOOL; LECTURER ON CLINICAL MEDICINE IN UNIVERSITY COLLEGE, LIVERPOOL.

SOME time ago my colleague Mr. F. T. Paul submitted to me for examination some of the urine of a patient whom he had seen in consultation with Mr. Owen Bowen of Liverpool. The circumstances of the case were briefly as follows.

The patient was a man who suffered from dilatation of the stomach and he felt great relief from his distress by taking magnesia. Carbonate of magnesium with bicarbonate of sodium was prescribed for him in moderate doses but he also took "powdered magnesia" on his own account, so that it is impossible to say how much he was taking altogether. Mr. Paul proposed to perform an operation, but the patient died quite suddenly, presumably from perforation of the stomach, a few days after his admission to the Royal Infirmary and no post-mortem examination was allowed.

The urine which was given to me was alkaline and it effervesced with acids, but it was quite free from any odour of decomposition. It deposited an abundant sediment consisting of sparkling crystals which under the microscope were seen to be elongated needles so extremely narrow that even under objective No. 7 Hartnach many of them seemed to fulfil Euclid's definition of a mathematical line. A considerable quantity of the deposit was collected, washed on a filter, and submitted to various tests. It dissolved completely in acetic acid without effervescence but was insoluble in alkalies. It yielded the reactions of a salt of magnesium, and after solution in dilute acid it gave a yellow precipitate with ammonium molybdate and with ammonio-nitrate of silver,—reactions which showed it to be an ortho-phosphate.



Crystals of monohydric magnesium phosphate in urine. From a micro-photograph by the author.

I may be permitted to recall the fact that ortho-phosphoric acid is capable of forming three orders of salts, according as one, two, or three of its hydrogen atoms are replaced by a metallic atom. Appended are the formulæ of the acid and of the three orders of salts which it can form by combination with sodium and magnesium respectively:—

H_3PO_4	Ortho-phosphoric acid.	Na_2HPO_4 $MgHPO_4$	Monohydric phosphate.
NaH_2PO_4 $Mg(H_2PO_4)_2$	Dihydric phosphate.	Na_3PO_4 $Mg_3(PO_4)_2$	Normal phosphate.

The monohydric and the normal magnesium phosphates are scarcely, if at all, soluble in water. They are readily distinguished from each other by heating them to 400° C. on platinum foil, when the monohydric phosphate is converted into pyrophosphate by the elimination of the elements of water, according to the following equation: $2MgHPO_4 = Mg_2P_2O_7 + H_2O$. The pyrophosphate, $Mg_2P_2O_7$, is recognised by its solution in dilute nitric acid giving a white precipitate with ammonio-nitrate of silver. Normal phosphate when heated undergoes no change.

The deposit which forms the subject of the present communication was shown to be a monohydric phosphate, by its undergoing the change into pyrophosphate when heated on platinum foil.

The occurrence of monohydric magnesium phosphate as a deposit in the urine is not alluded to in any of the ordinary text-books, neither is it mentioned in Huppert's last edition of Neubauer and Vogel's great work on the urine, nor in Rieder and Delépine's more recent "Atlas of Urinary Deposits." Both these works, however, admit the occasional appearance of crystals of trimagnesium (normal) phosphate as a rare occurrence.

It seems obvious that the magnesium forming the deposit in the present case was derived from that which had been swallowed for the relief of the gastric distress. Owing to the dilated condition of the stomach we must conclude that its contents were unduly retained, so that the salts were absorbed into the blood instead of passing on into the intestines and thence escaped through the kidneys

I have examined the urine in several instances in which magnesia was being taken, some being cases of moderate dilatation of the stomach, but have failed to find any deposit of the kind I have described; I have also analysed several phosphatic calculi in the museum of University College, Liverpool, but have not succeeded in finding any of the monohydric magnesium phosphate as a constituent.

Apart from the interest attaching to all abnormal states of the urine I think that the present communication is not without its bearings on practical medicine. In the first place, unless the nature and mode of origin of these crystals[1] were understood their discovery in the urine might give rise to misapprehension and perhaps to groundless alarm in the mind of the physician, and, secondly, their presence seems to indicate that the stomach meets with difficulty in emptying itself and so might suggest the existence of serious organic disease.

Finally, we have to ask ourselves, in the light of the present case, whether these crystals may not sometimes coalesce so as to form massive concretions, whether, in fact, the free administration of magnesia may not be an occasional factor in the production of phosphatic urinary calculi.

Liverpool.

---

[1] These crystals were demonstrated and described before the Royal Medical and Chirurgical Society of London on Nov 27th 1900.

A CASE OF OVARIAN TUMOUR WITH SPONTANEOUS RUPTURE AND ŒDEMA OF THE LEGS SIMULATING MALIGNANCY

By SMALLWOOD SAVAGE, M.B., B.CH. OXON.,
F.R.C.S. ENG.,
SURGEON TO THE BIRMINGHAM LYING-IN CHARITY AND THE WOLVERHAMPTON HOSPITAL FOR WOMEN

A PATIENT, single, aged 61 years, was sent to me in January, 1902, by Mr F. J. Hart of Much Wenlock complaining of an abdominal swelling and œdema of the legs. She stated that she had had the change of life eight years previously when she was 53 years of age, that five months previously she had noticed a stiffness and for two months a swelling in the abdomen which had latterly increased very considerably in size. During this same period both legs had become very œdematous which had rendered locomotion difficult and in consequence had confined her to bed. There was no history of any injury or fall but in November pain was complained of in the region of the umbilicus with difficulty in the opening of the bowels. For many years weakness of the bladder had given trouble, producing at times retention of urine with incontinence. On examination the patient, who was naturally spare, was seen to have a large abdominal tumour rising from out of the pelvis and on palpation it was felt to reach to one inch above the umbilicus, it was hard, tense, and fluctuating in places. Above the tumour and in the right hypochondrium and loin fluctuation was obtained as of free fluid in the peritoneal cavity. By vaginal examination the tumour was felt in front and was found to be displacing the uterus backwards. Both legs were markedly œdematous, especially the right. There were no enlarged glands to be felt or prominent veins on the abdomen to be seen, nor was the abdominal wall œdematous. The urine was pale, neutral, and contained no albumin or sugar. The diagnosis made was one of malignant ovarian tumour with free fluid in the peritoneal cavity and pressure on the iliac veins. At the operation on Jan. 17th, on opening the abdomen, colloid material of gelatinous consistency and amounting to about one pint was found free in the peritoneal cavity. A large trocar was inserted into the tumour but owing to the fluid being too viscid it would not run, so that it had to be removed by ladling it out with the hand. The tumour was a left-sided multilocular ovarian cyst and its pedicle was ligatured in the usual way, the pedicle was not in any way twisted. The peritoneal cavity had to be flushed in order to bring up to the surface the remnants of the sticky lumps of colloid. The peritoneum was everywhere injected, covered with lymph, and showing the results of slight peritonitis. The right ovary was small and atrophic and was not removed. The patient made a satisfactory recovery from the operation, only during convalescence catheterism had to be resorted to on account of the weak and atrophic condition of the bladder. Pathologically the tumour was a glandular multilocular cyst of the left ovary; the contents consisted of a thick tenacious colloid and amounted to about half a bucketful, on most careful examination no point of rupture of the cyst wall could be detected.

The case is interesting and worthy of record on account of (1) the spontaneous rupture of the cyst, allowing of the escape of some of its contents into the peritoneal cavity; (2) œdema of both legs as a pressure symptom, and (3) the difficulty in diagnosis.

1. Rupture of an ovarian cyst is not often met with in a simple tumour, owing to the fact that all such cases are recognised and are dealt with early and before the tension of the fluid within the cysts has reached the point of rupture. In this case the cyst wall was found to have been distended and thinned out in several places. In the absence of any history of injury or fall, this complication must be called "spontaneous" as opposed to "traumatic," and may be accounted for by the rapidity of growth of the tumour with increased tension of its contents. It seems probable that the colloid had been free in the peritoneal cavity for two months, for at this time complaint was made of pain in the umbilical region together with great difficulty in obtaining an action of the bowels, and this was further borne out at the time of the operation when a peritonitis of some weeks' duration was observed, the presence of simple colloid in the abdomen in the absence of any bacterial infection having produced a simple inflammation of the peritoneum with no constitutional poisoning effects. This fact is of particular interest to the abdominal surgeon and it demonstrates that cyst contents and the like of a simple nature are perfectly harmless provided that germs have not been introduced from without.

2. Œdema of both legs as a pressure symptom is not often seen nowadays for the same reason as that before mentioned. The cause of the œdema was on account of the heavy weight of the tumours pressing on the iliac veins, the contents being large in amount and thick, if not semi solid, in consistency, and this explanation seemed satisfactory when on removal of the tumour the œdema soon disappeared.

3. With regard to the third point the diagnosis made of this case was one of malignant disease of the ovary which rested on (*a*) the rapidity of growth, for according to the history a swelling of the abdomen had been noticed for two months only although a "stiffness" had been felt somewhat longer, (*b*) the hard firm character of parts of the tumour suggestive of solidity of growth, (*c*) fluctuation above the tumour, as of free fluid in the peritoneal cavity, a condition which of itself is highly suggestive of malignancy although met with in some simple enlargements of the ovary; and (*d*) œdema of the legs, a symptom more often met with in malignant ovarian than in simple tumours although not pathognomonic of malignancy.

"IDIOPATHIC," OR CONGENITAL, HEREDITARY AND FAMILY HÆMATURIA[1]

By LEONARD G. GUTHRIE, M.D. OXON., F.R.C.P. LOND.,
SENIOR PHYSICIAN TO THE PADDINGTON GREEN CHILDREN'S HOSPITAL; PHYSICIAN TO THE HOSPITAL FOR EPILEPSY AND PARALYSIS REGENT'S PARK.

IDIOPATHIC hæmaturia is not mentioned in text-books nor have I found any reference to it in medical literature. Dr W. H. W. Attlee, however, has recorded "three cases of recurrent hæmaturia occurring in one family"[2] which I believe to be of the same nature as those which form the subject of this paper. The "essential renal hæmaturia" of

---

[1] A paper read before the Harveian Society of London on April 24th, 1902.

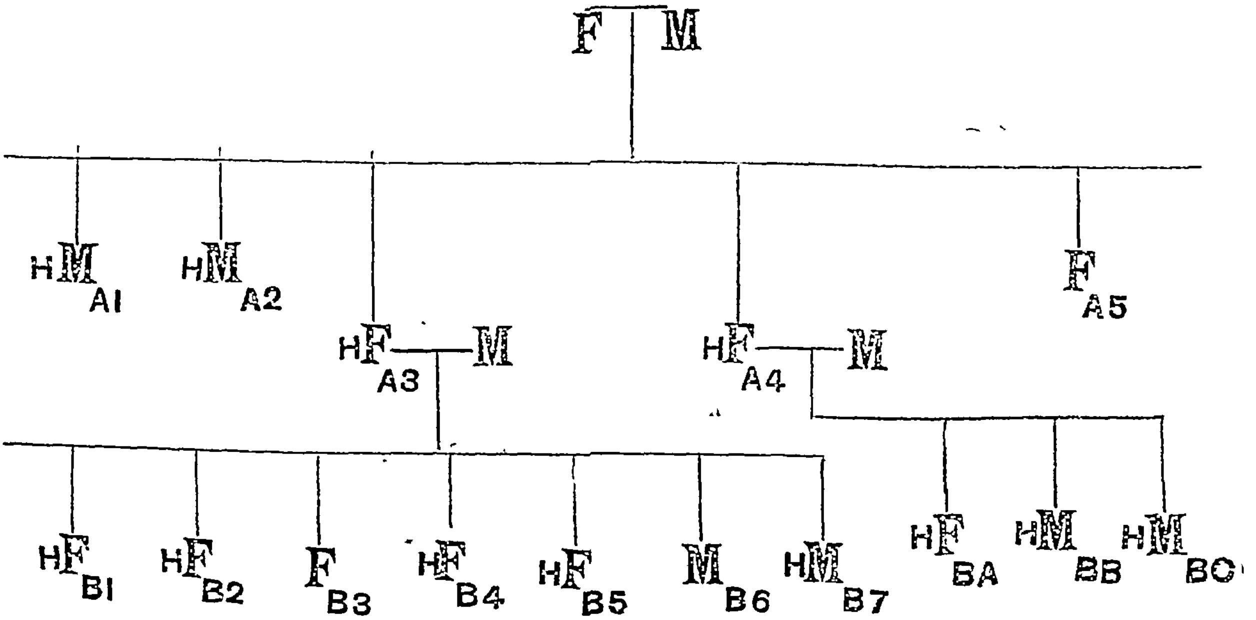
[2] St. Bartholomew's Hospital Journal, December 1901

Debairieux, in which hæmorrhage occurs from apparently healthy kidneys, is doubtless closely related to idiopathic hæmaturia, but lacks the hereditary congenital and familial characters of the latter affection.[3]

I have knowledge of the existence of idiopathic hæmaturia in 12 persons. Eight of these are brothers and sisters or first cousins. Their mothers are two sisters who are themselves subject to this complaint. These two sisters had two brothers, both of whom were similarly affected. The complaint is therefore familial and hereditary but at present has only descended to the second generation. It is impossible yet to say whether it may or may not be further transmitted. Seven of those affected have been females and five males. So far as my own cases are concerned, hæmaturia has only been inherited through the maternal side, but Dr. Attlee's cases (to which further reference will be made) suggest that it may also be inherited from the male parent. In all my cases it appears to be congenital or has been noticed shortly after birth. The first generation of the two families mentioned consisted of two brothers and three sisters, all of whom, except one sister, have been liable to hæmaturia from birth. The two brothers died between 20 and 30 years ago, aged four and a half and 11 years respectively. The exact cause of their deaths cannot be ascertained. The two sisters affected are now aged 40 years and 30 years respectively, are married, and have issue. The elder has seven children, of whom four girls, aged 18, 15, 13, and 10 years, and one boy, aged six years, are subject to hæmaturia, whilst one girl and one boy escape. The younger sister has two boys, aged eight years and three years respectively, and one girl, aged 11 years, all of whom are affected. The third sister, who is free from the complaint, is unmarried. The eldest daughter of the elder married sister suffers from eczema and spasmodic asthma as well as from hæmaturia. The third daughter has had attacks of epistaxis and hæmatemesis but no hæmaturia. Gout and rheumatism are said to exist on the maternal side of these families but no other family complaint. The relationship of the persons affected is shown in the annexed table of descent.

The characteristics of idiopathic hæmaturia may thus be summarised: 1. It is hereditary, familial, and congenital. 2. The hæmaturia may be persistent for many years but may vary in extent. In some cases it may cease for a time, but in all it is apt to recur or to increase in paroxysmal attacks or exacerbations. For instance, in one of my cases the urine examined almost weekly for upwards of two years has never failed to contain blood visible to the naked eye and to give a marked reaction with ozonic ether and guaiacum. Its colour varies from that of old gold tinged with red to the bright scarlet of oxyhæmoglobin. In another, blood is always present but can only be detected on microscopical examination except when exacerbations occur. At these times the urine may resemble almost pure arterial blood. It is not "smoky" in appearance but is "red," the colour being due to oxyhæmoglobin not methhæmoglobin. Normal red blood corpuscles and blood casts can always be found under the microscope; so the colour is not due to hæmoglobinuria. The amount of blood passed during exacerbations is always far greater than is ever seen in cases of nephritis, and resembles in profuseness the blood passed in cases of renal calculus or new growth. 3. All cases are liable to paroxysmal exacerbations of hæmaturia which are usually accompanied by slight pyrexia, malaise, headache, vomiting, and slight pains in the back or limbs. The exacerbations are often attributed to "catching cold" and are associated with slight bronchial catarrh, or with trivial ailments, such as toothache, earache, or tonsillitis. In some cases articles of diet—such as black currants, asparagus, strawberries, claret, and perhaps rhubarb—have been held to produce them. But the exacerbation may occur without complications and in the absence of special causes. The duration of these exacerbations is usually several days but seldom exceeds a week or at most a fortnight, and after the first few days the blood gradually lessens in amount. They have no law of periodicity or of frequency. They may occur at intervals of weeks, months, or years, but they appear to become less frequent after the first decade has been passed. They occur with extreme suddenness by day or by night and are not influenced by posture. Extremes of hot or cold weather seem to give rise to them. 4. Idiopathic hæmaturia is not associated with œdema nor with ascites nor with the cardio-vascular changes following ordinary nephritis. Except at times when exacerbations occur the subjects appear to be, and are, in perfect health. There may be temporary anæmia after an exacerbation, but it is not profound or lasting. 5. The hæmorrhage is not due to the presence of uric acid or of oxalates. A few crystals of these substances may

TABLE OF DESCENT.



In the above table F = female and M = male. The first pair had five children marked A_1, A_2, and so on. Of these 5 children those marked H in addition suffered from hæmaturia. Two females of the A group—namely, A_3 and A_4—both being hæmaturic, married and had children. A_3 had 7 children marked B_1 and so on. Of these 7 children 5 are hæmaturic. A_4 had 3 children marked BA, BB, and BC, all of whom are hæmaturic.

I have personal acquaintance with only three members of the families—namely, with the elder married sister and with her second daughter and youngest boy. I am informed by their medical attendant that the second married sister and her three children, whom I have not seen, are liable to attacks of hæmaturia which in all respects resemble those which affect my own patients.

---

[3] Cf. also Dr. J. H. Bryant, Clinical Journal, July 25th, 1900, p. 214.

often be found on microscopical examination, but free gravel is never passed, neither is there any excess of uric acid in solution The amount of urea passed is normal. 6. The specific gravity of the urine is not unduly low. It varies from 1015 to 1030 The quantity of urine passed is not above nor below normal. The reaction is acid or neutral. The urine is nearly always albuminous, the albumin varying from one twentieth to one fourth of its bulk. Sometimes it is in accordance with the amount of blood present, at others it exceeds it. Nucleo-albumin is usually passed as well The sediment nearly always contains free normal red blood corpuscles and tubular blood casts in more or less abundance, but never hyaline casts Finally, none of the subjects of idiopathic hæmaturia is a "bleeder." One of them recently had some adenoid vegetations removed and the hæmorrhage caused was neither profuse nor prolonged None of them suffers from Raynaud's disease or from purpura. Scarlet fever can be excluded as a cause in all cases and also calculus, new growth, congenital syphilis, renal tuberculosis, and all forms of nephritis The kidneys are not moveable, palpable, nor tender, and there is no definite nor constant local pain.

CASE 1.—This patient, now aged six years, has been under observation for three years He was nursed until he was nine months old and was then fed on Savory and Moore's food and cow's milk At the age of three months he suffered from slight eczema of the scalp and face, seemed weakly, and had occasional attacks of diarrhœa and vomiting From the first his urine was noticed to be blood red in colour from time to time. But this attracted little attention as it was known to be a family affection. Advice was sought chiefly because of nocturnal and diurnal enuresis and frequency of micturition. He is a healthy-looking, ruddy and chubby child, full of life and spirits. The heart and pulse are normal, the kidneys are not palpable There is no renal tenderness nor pain and no trace of œdema at any time The urine examined at almost weekly intervals for about two years has never been free from blood. Reaction is subacid or neutral Its specific gravity is from 1015 to 1030 The colour varies from old reddish gold to bright blood red. The blood is always discernible by the naked eye. The urine is never smoky in appearance and Dr Archibald E. Garrod, who kindly examined it, found that the colour was due to oxyhæmoglobin, not methhæmoglobin. Uric acid is never passed as gravel, and quantitative analysis by Dr Garrod showed it to be diminished rather than increased in solution. He estimated the total amount passed in 24 hours as 0·150 gramme on one occasion and 0·1629 gramme on another (Hopkin's method was used) 100 cubic centimetres contained 0·0410 gramme of uric acid on one occasion and 0·038 gramme on another The deposit usually contains a few crystals of uric acid or oxalates, many red blood corpuscles and blood casts, but no hyaline casts. The total quantity passed is not above the average. Albumin is always present in quantities varying with the amount of blood present. The average content of albumin is about one-twelfth The urine almost always contains nucleo albumin as well. During the past three years the child has had periods, lasting about a week and occurring every two or three months, in which the blood is greatly increased in amount. I have never seen him at such times, but gather from his mother's description that he has usually some slight malaise, his tongue becomes furred and he may be restless and may scream in his sleep. The exacerbations of hæmaturia are often preceded and accompanied by enuresis and frequency of micturition. They are often associated with "catching cold" or some slight ailment such as toothache or earache. After vaccination the urine was said to improve in appearance as the arm got better On the other hand, during an outbreak of eczema the urine was not dark until the rash was fading Pertussis, which he had for six weeks, "did not upset him nearly as much as might be expected" Influenza increased the flow of blood. Extremes of hot or cold weather always render him more liable to attacks The hæmaturia is not more marked in diurnal than in nocturnal urine The effect on his general health does not seem to be great. His mother says that "his spirits never seem to fail; he is as bright and merry as possible even when the urine is very bad." The attacks do not seem to be induced by any particular articles of diet except by strawberries and asparagus. Black currants, which used to produce hæmaturia in his brother and in two sisters had no effect on him. Gooseberries, raspberries, and grapes agree with him; rhubarb has never been given to him. He seems to thrive on ordinary diet

Treatment—Hazeline, oil of turpentine, calcium chloride, and gallic and sulphuric acid have been used without much effect on the hæmorrhage The only drug which seems to cut short the attacks is substantia supra renalis in one and quarter grain doses three or four times a day Urotropin seemed to increase frequency of micturition and incontinence, but these discomforts are speedily relieved by a few doses of tincture of hyoscyamus with citrate of potash and infusion of buchu. Beyond keeping him indoors and lying down during the exacerbations little has been done and more seems unnecessary in the way of treatment.

CASE 2.—This patient, now aged 15 years (the sister of the patient in the preceding case), has also been under observation for three years. The urine examined on many occasions during that time has never failed to contain blood and albumin, but as a rule the blood is less in amount than it is in the previous case and there is rather more albumin. The average amount of albumin is about one-tenth, sometimes it falls to one twentieth part. Nucleo-albumin is also present. As a rule the blood can only be detected by microscopical examination, when fragments of blood casts and blood corpuscles are found, but no hyaline or true granular casts. The reaction is acid or neutral The specific gravity is from 1015 to 1025. Free gravel is never passed and Dr Garrod estimated the quantity of uric acid in solution as about the same as in the previous case—namely, at about 0·0412 gramme in 100 cubic centimetres The patient had a typical attack or exacerbation of hæmaturia two years ago but never since. The practitioner who then saw her kindly sent me the following particulars In February, 1900, she had a severe sore throat which, however, lasted only a few days and she then seemed to be well There was no rash and she had had scarlet fever four years previously About a week after the throat became well the urine was noticed to be getting darker and a night or two later she was violently sick and she passed a quantity of bright scarlet urine which was practically pure blood. The tongue was brown and dry, the temperature was 102° F., and she complained of headache, but of no other pain. The temperature gradually fell and the urine regained its normal appearance in about a fortnight. There was never any trace of œdema She is a well grown and fairly healthy looking girl, though slightly anæmic. The heart is normal in position, size, and sounds The pulse tension is not unduly high The kidneys are not palpable nor is there any renal tenderness. Quite recently she has had some adenoids removed The hæmorrhage was not excessive or prolonged, which disproves the existence of hæmophilia in this case. The hæmaturia was not affected by the operation. She prefers butcher's meat to any other article of diet and cannot take milk without a tendency to vomiting Black currants are said to induce major attacks of hæmaturia in her case as in other members of the family Of the other members of the family I can say but little. The mother of the patients (Cases 1 and 2), who is now aged about 40 years, states that as long as she can remember she has been subject to such attacks as her children have had and that as a child she was always considered delicate in consequence The attacks, she says, were always produced by black currants or by claret, but they occurred also in presence of any ordinary slight ailment. The last occasion on which severe hæmaturia occurred was six years ago, shortly after the birth of her youngest child (the patient in Case 1). She has not had any further attack of hæmaturia since then. She has not complained of being out of health, as far as I know, for the last three years, and she always appears to be well, active, and energetic.

Other cases of apparently similar nature—Dr Attlee gives in the paper to which attention has been drawn in the beginning of this article a succinct account of three cases of recurrent hæmaturia occurring in one family The patients were females, aged five and a half, four and a half, and two years and four months respectively, and were admitted to the Metropolitan Hospital under the care of Dr Arthur D Davies and Dr A Haig during the year 1901. The father died, aged 30 years, from uræmia. The mother seemed to be a perfectly healthy woman. All these children were well nourished and they appeared to be in perfect health Scarlet fever could be excluded in all of them and none exhibited any definite signs of nephritis or of cardio-vascular changes. Calculus could be excluded and also new growth and tuberculosis in all cases. One of them, aged four and a half years, had four attacks of hæmaturia in which the urine became bright-red between April and December, 1901. The child had been subject to epileptic fits since the age of 11 months but the hæmaturia was preceded by a fit on one occasion only. The attacks of hæmaturia were ushered in by malaise, sometimes by pain in the legs, or by vomiting and slight pyrexia. A typical exacerbation is thus described after a period during which the child had seemed quite well except that the urine contained a faint trace of blood: "On Dec. 29th, 1901, she suddenly complained of not feeling well. She had no pain and no fit. The temperature rose to 101·8° and about six hours afterwards the urine was again bright-red. The temperature kept up for two days, then became normal and continued so. The blood decreased to a mere trace and then remained stationary." The urine was always acid and averaged 20 ounces per diem. The specific gravity was from 1026 to 1015. Albumin and blood were always present and occasionally granular casts.

Another of these sisters, aged five and a half years, was admitted to hospital on May 20th, 1901. On May 16th she complained of headache and pain in the right side of the chest and she vomited three times. On admission she had slight bronchitis, the temperature was 100 6° F., and the urine was smoky, acid, of specific gravity 1017, and contained a cloud of albumin and a considerable amount of blood, blood corpuscles, and blood casts, but no crystals. After five days the temperature became normal and remained so; the urine contained no blood after June 6th but a trace of albumin. In the following December the urine contained a cloud of albumin and blood but nothing else was found under the microscope.

The third child, aged two years and four months, vomited twice on May 31st and again frequently on June 1st, when her temperature rose to 101·8° F. On the evening of that day the urine was found to be scanty, loaded with albumin, and to contain much blood. The pyrexia continued until June 4th when the temperature gradually fell to normal. The amount of blood rapidly decreased and on June 6th there was none to be found but a trace of albumin existed until her discharge from hospital on July 8th. The urine was always acid and the specific gravity averaged 1017. A fair quantity was always passed after June 5th. Granular and epithelial casts were passed on two occasions but no crystals.

There can be little doubt that these cases are of the same nature as my own. It is true that evidence of the congenital tendency to hæmaturia is wanting, the youngest child being of the age of two years and four months when hæmaturia was first noticed. But hæmaturia may have existed long before, though in so slight a degree as to escape detection. The amount of blood present in the urine in my second case was so small for several months after the patient first came under observation that I doubted whether she shared the family proclivity until the typical attack of profuse hæmaturia took place. The fact that the father of Dr. Attlee's patients died, aged 30 years, from uræmia is of significant interest. It is possible that he also suffered from idiopathic hæmaturia. If so the prognosis in such cases must be guarded although the affection does not seem to endanger life or even health as a general rule. It will be observed that in Dr Attlee's patients the inheritance is from the father and not from the mother as in my own cases.

The explanation of these mysterious cases remains to be discussed. The fact that the hæmaturia is congenital, or at all events, noticed shortly after birth, excludes all the ordinary or known causes of such hæmorrhage. The most reasonable supposition is that there is some inherent weakness or varicosity of the walls of the renal vessels leading to what has been called renal hæmophilia[4] or renal epistaxis. Or the vaso-motor system may be at fault (angio-neurosis), in which case the complaint might be grouped with cyclical or postural albuminuria[5] But, as already mentioned, the hæmaturia is in no sense postural. The exacerbations occur as often during the night or whilst the patient is at rest in bed as by day when he is up and about.

The diagnosis of idiopathic hæmaturia rests on the personal and family history; on the occurrence of the febrile exacerbations in which the hæmaturia far exceeds that of acute nephritis; on the absence of œdema, dropsy, and cardio-vascular changes; and, finally, on the absence of any of the well-known causes of hæmaturia.

Upper Berkeley-street, W.

SCURVY DEVELOPING IN A RICKETY BOY, AGED FIVE AND A HALF YEARS.[1]

BY GEORGE CARPENTER, M.D. LOND.,
PHYSICIAN TO THE EVELINA HOSPITAL FOR SICK CHILDREN.

THE patient, a boy, aged five and a half years, whom I saw for the first time on Feb. 24th, 1902, was breast-fed but was not weaned until 18 months of age. When at the age of 12 months he began to walk he was found to be rickety. According to his mother he was always "too heavy for his legs" which were gradually becoming more and more bent. About nine months previously he commenced to complain of pain in the arms and chest and especially in the legs and he did not like to be touched; he attended school, however, up to within six months before. He last walked six weeks previously, when he hobbled from one chair to another, but latterly he had reclined in one position, either in bed or on a chair. For the most part he was kept indoors and had been gradually getting paler. For about a week he had cried on passing urine but no blood had been detected in it. He had always been constipated; the motions were free from blood. He had always had peculiar ideas about his food. He would eat bread-and-sugar and occasionally a little butter, but he objected to milk, though he could drink tea with milk in it. He ate fried or roast meat but the meat had to be dry and he would not touch gravy or meat-juice. Vegetables always refused—they made him sick—and he had never ca fruit of any kind. He liked suet pudding and took mi puddings occasionally. Apart from what has been relat nothing worthy of note occurred as regards infantile d orders. His father and mother had both suffered fro rheumatic fever. He had four brothers and sisters, tw being older than himself, and the youngest was an infan three months old.

On examination the patient was found to be a well-nourished, placid, anæmic child who remained quiet if undisturbed but when the couch was moved or his body was approached for examination he cried out. His legs were flexed on the thighs and the thighs on the abdomen. There was very decided tenderness all over the trunk and limbs, especially the legs. The front of the left shin had lost its sharp outline and was nodulated and the bone was bowed. The right tibia was decidedly bowed and its free edge was thickened. When he was not paying attention the shin-bones could be squeezed without causing him pain. The femora were not thickened. When his attention was drawn to the fact that they were being manipulated he cried out, but not otherwise. His muscles were flabby, especially those of the legs; they were free from indurations. The tenderness and paretic condition of the lower extremities of the child, combined with his behaviour, led me to suspect scurvy and to examine his mouth, although no complain had been made of this. The mucous membrane general was pale. At the junction of the incisor, the canine, an the first temporary molar teeth with the gums there was thin broken line of purple discolouration which broadened out at the last mentioned teeth and over the second molar teeth expanded into a purple epulis-like overgrowth of the gums which almost obliterated these teeth The gums did not bleed on pressure. The body was covered with petechiæ, mostly, apparently, originating in flea-bites, and there was a small bruise over the left shin. The head was large but was not characteristic of rickets and the anterior fontanelle was closed. The ribs were beaded and displayed a prominent rosary but in spite of this the chest was of fair shape. The ends of the wrists were knobby and the ankles and knees were obviously enlarged. The long bones of the lower extremities were bent and the curves fitted into one another when the limbs were in a position of rest. The femora were bent antero-posteriorly at the junction of the lower and middle thirds and the tibiæ at the lower third So far as could be determined by a physical examination all the patient's organs were healthy An examination of the blood showed in the fresh films typical rouleaux formation and an absence of microcytes and poikilocytes; stained films appeared to be normal The red blood corpuscles numbered 4,733,000 per cubic millimetre, or 94·6 per cent. The hæmoglobin was 60 per cent. and the colour index was 0·7. The white corpuscles numbered 8300 per cubic millimetre, a ratio of 1 in 570 The boy was admitted to the hospital under my care on Feb. 24th. With the varied diet he obtained there, which he was compelled to take, coupled with orange-juice, the gums quickly recovered, and by March 16th the limbs were quite free from tenderness but he could not stand without assistance

---

[4] Senator, Broca, Passet.

[5] Mr. Harry Fenwick has found varicosity of the papillary plexus in cases of painless unilateral hæmaturia in young adults and has cured them by papillectomy. (Brit. Med. Jour., vol. i., 1900, p. 248).

[1] A paper read before the Society for the Study of Disease of Children on March 21st, 1902.

This case of characteristic scurvy of infantile type is interesting by reason of the age of the patient. Such cases mostly arise between the ages of seven and 14 months, and usually about the ninth or tenth month The youngest case recorded by Dr A. Matheson of Neillsville, Wisconsin, was in an infant only three weeks old; it was breast-fed and the case ended fatally. After two years of age it is decidedly quite out of the common to meet with such an instance as that just recorded with its typical gum lesions Although this is so I do think—and I would again call attention to the fact—that some of the cases met with in older children suffering from "*simple* hæmaturia" (let me call it this for want of a better description), as also some cases of purpura, mostly unaccompanied by gum lesions and thereby passing unrecognised, are solely due to a deficient dietary, and are therefore essentially scorbutic in origin. These children are undoubtedly cured by a change to a proper mixed dietary in the hospital wards without any adjuncts. I have seen this over and over again Members of the Society for the Study of Diseases in Children may possibly remember that last year I called attention to this when Mr. D'Arcy Power showed a case of paroxysmal hæmaturia in a boy nine years of age which in the sequel was proved to be an undoubted case of scurvy by reason of a subsequent but tardy development of spongy gums. Further, so marked a case of active rickets at this period of life is unusual and it is of interest from that point of view also, although its association with scurvy must be looked upon as an accidental one merely. Children with scurvy are not necessarily rickety, though rickets is found in about half the number of cases coming under observation, nor are they necessarily anæmic, though in this respect they are more often so than not.

Regarding the etiology of infantile scurvy it is thought on all sides that the chief, if, indeed, not the only, cause is a dietetic one. In the case of this child, for instance, there can be no doubt that his dietary was a restricted and an unnatural one by reason of the absence of fresh vegetables or their equivalent. He did, however, take milk occasionally in the shape of milk-puddings and mixed with his tea, and he did, according to his mother, have meat twice a day, though it is stated that he liked his meat "dry" This child, apart from his fads as regards food, had similar food to that of the other children at home who remained perfectly healthy under a more varied *menu*.

A study of reported cases, coupled with a clinical experience spreading over a period of years, makes it clear to my mind that no single article of diet is capable of producing scurvy with certainty, though it is abundantly clear that the various proprietary foods and milk-preparations are flagrant offenders. The personal element in the case of infants and children has always to be taken into consideration, for it is a not unimportant factor in determining the onset of this disorder Thus several infantile members of a family may be suitably reared on a diet which proves eminently scorbutic to another infantile member of that family Even infants at the breast, and newly-born infants too, have developed scurvy, though this is not a common occurrence. Yet fresh breast milk is deemed to be eminently anti-scorbutic and it is certainly free from the ptomaines of decomposition, though in other respects it may be quite unsuitable as a food for the purpose of rearing a healthy child. Undoubtedly many articles of diet which have been administered over long periods of time are capable of producing scurvy in some infants and, equally undoubtedly, they will not do so in the majority of others. Infantile dietetic errors are the rule, but it is only exceptionally that a case of scurvy comes under observation, one unfortunate amongst the many that escape Thus a diet of sterilised milk, simple boiled milk, pasteurised milk, pasteurised percentage milk mixtures, peptonised milk, condensed milks, malted milks, desiccated milks, the numerous proprietary foods, and cereal gruels combined with the above milk-preparations, each in turn or in combination has produced scurvy in those prone to that disorder though harmless in that respect to others According to Rosenthal people amongst whom he practises have a method of feeding their children from very early life on *zwieback*—a food similar to toasted sweet bread—nothing else (not even milk) for a time and these children after three or four months of this diet show signs of scurvy.

Further, it has been proved, in a considerable number of cases, that the addition of orange-juice, or fruit-juice, or beef-juice, to some of the above dietaries which have been proved to be scorbutic, has been quite sufficient to cure the complaint. On the other hand, there is the fact that anti-scorbutic articles, in the shape of potatoes and bananas, have been taken, where milk was seldom drunk or meat was eaten, but were not successful in the face of so defective a dietary in warding off the disease. In the case of some infants a mere change of diet, and that not always *prima facie* an ideal one, and without beef-juice or fruit-juice, has proved successful in bringing about a cure The judicious combination, however, of fruit-juice and a rational dietary must be looked upon as a specific and the rapidity of the cure in such cases is most striking

Does the view of Torup of Christiania that scurvy is due to ptomaine poisoning from tainted meat, and that the fact that fresh vegetables and lime-juice are a part of the dietary is not sufficient to prevent or to cure scurvy, satisfactorily explain cases of infantile scurvy? It is a view which has much to recommend it, for it has been fortified by Arctic experiences and has, moreover, been confirmed by the experiments of Mr F G Jackson and Dr. Vaughan Harley on monkeys[1] One's clinical experience of infantile scurvy, combined with a study of the histories of numerous fully reported cases scattered through literature, do not favour the acceptance of Torup's views on adult scurvy in explanation of its etiology.

It would appear that in infantile scurvy we can go no further at present than to say that the fault lies mainly in the diet but not from a ptomaine point of view, and the more the food departs from what is natural and the more prolonged is the use of such a faulty food, the more likely is it to produce scurvy But for reasons already given there must be a personal factor in these cases. The diet prescribed may not be appropriate for the particular child for whom it has been designed, certain foods are specially obnoxious to certain children and of these harmful foods the proprietary foods hold the pride of place.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

TWO CASES OF ABSCESS IN THE TEMPORO-SPHENOIDAL LOBE PRESENTING NO LESION IN THE EARS.

(Under the care of Dr D B. LEES.)

ABSCESS of the temporal lobe of the brain is so commonly consecutive to suppuration in the middle ear, that it is desirable to record instances where no ear lesion is present. In the following cases there was necrosis of a small portion of the petrous bone, but the middle ear appeared to be perfectly healthy Septic organisms may have been conveyed to the petrous bone and to the brain from a transient otitis externa, which is not uncommon in children. Mr. C. Mansell Moullin described a case at a meeting of the Clinical Society of London,[1] in which an abscess was found in the temporal lobe although there was "no sign of middle ear disease."

---

[1] THE LANCET, April 28th, 1900, p. 1184.

CASE 1.—A girl, aged six years, was admitted into the Hospital for Sick Children, Great Ormond-street, on Nov. 14th, 1901, under the care of Dr. D. B. Lees. For two months before admission she had suffered from frontal headache and earache and for the last month from vomiting. On admission her attitude was one of cerebral irritation with evidence of marked photophobia. She complained of severe intermittent pain in the right frontal region. No paralysis or rigidity was present but there was optic neuritis on each side, which was more advanced on the right side. Percussion of the head elicited tenderness only over the right side of the forehead. The tympanic membranes were normal and no discharge from the ear was found. The child's condition remained about the same till the morning of Nov. 25th, when she died suddenly.

Necropsy.—At the post-mortem examination an abscess containing about two ounces of greenish inodorous pus was found in the right temporo-sphenoidal lobe, with rough walls of some thickness and consistence. On the dura mater, facing its point of nearest approximation to the surface and overlying the external auditory meatus about half an inch from the tympanum, was a hiatus a quarter of an inch in diameter with discoloured margin, leading to a necrotic depression in the bone. On chiselling away the latter the underlying lining membrane of the meatus was found to be normal. The dura mater over the middle-ear was normal and the cavity of the latter and the mastoid cells contained only a trace of clear mucus, the walls and ossicles showing no change. The organs in other parts were healthy. A pure culture of the streptococcus pyogenes was obtained from the pus.

CASE 2.—A girl, aged one and three-quarter years, was admitted into Dr. Lees's ward on July 16th, 1896. Three months before admission she had suffered from vomiting and "used to put her hand to her head and cry out." For three weeks before admission she had lost the use of her limbs, a condition which was ushered in by a fit. The child was drowsy, with bulging fontanelle, and presented a left-sided hemiplegia. A double internal squint subsequently appeared but no optic neuritis. Death occurred on August 16th.

Necropsy.—The post-mortem examination disclosed an abscess of the size of a hen's egg in the right temporo-sphenoidal lobe with tough walls and containing thick, greenish pus. Some amount of basic meningitis was also present. The brain and membranes were adherent to the right great wing of the sphenoid and the right petrous bone showed a small patch of disease of about the size of a threepenny-piece above the tympanum. The middle-ear on this side was healthy and the membrana tympani was clear and thin. Otherwise the body showed no abnormality.

Remarks by DR. LEES.—In each of these two cases an abscess in the right temporo-sphenoidal lobe apparently resulted from necrosis of a small part of the petrous bone, without any affection of the tympanic cavity or mastoid cells. It is, however, to be regretted that the temporal lobe and petrous bone had not been removed together and placed in formalin before it was attempted to trace the path of the suppurative infection. In the case first narrated the necrosed part of the petrous bone lay over the external auditory meatus and in the earlier case it lay over the tympanum. In both cases the underlying mucous membrane was healthy and it seemed probable that the bone was the primary seat of disease. The cases prove that necrosis of the petrous bone and temporo-sphenoidal abscess *may* exist when there is no otorrhœa and the tympanic membranes are normal—a fact of great importance in diagnosis.

VICTORIA HOSPITAL, FOLKESTONE.

A CASE OF ACUTE INTESTINAL OBSTRUCTION DUE TO EMBOLISM OF BRANCHES OF THE SUPERIOR MESENTERIC ARTERY.

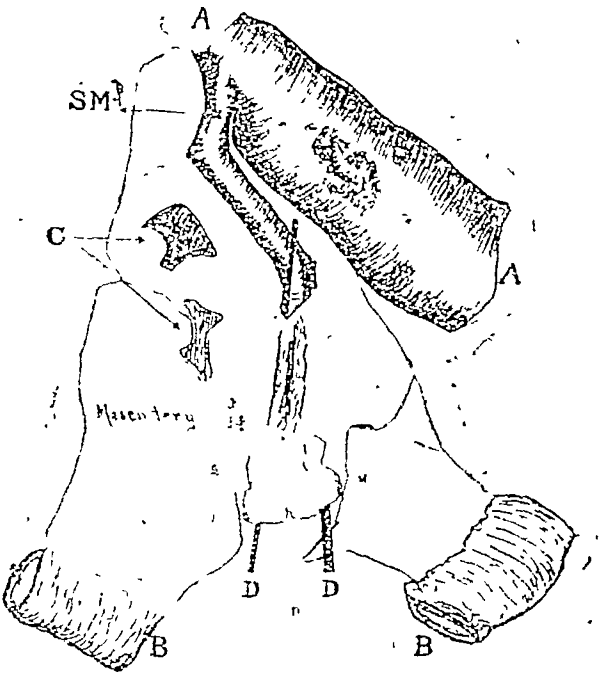
(Under the care of Dr. W. J. TYSON and Mr. W. W. LININGTON.)

EXTENSIVE interference by thrombosis or embolism with the circulation of the bowel leads to symptoms of intestinal obstruction owing to the resulting paralysis of the muscular coat of the gut. The recorded cases are not numerous and the condition has never been diagnosed before operation.

A married woman, aged 66 years, was first seen by Mr. Clifford Hackney on March 5th, 1901. Her symptoms were slight pain over the liver, constipation, sickness, and a little epigastric tenderness; these had been present for two or three days. The temperature was normal. On the 7th she stated that she felt better, the bowels acted two or three times comfortably, there was less flatulence, but she was still sick, the vomit being of a greenish colour, watery, and free from odour. On the next day the sickness became worse and abdominal distension appeared, the bowels were confined, and the general condition was much worse. The notes of the history of the case were kindly supplied by Mr. Clifford Hackney, with whom Dr. Tyson saw the case in consultation at Hythe on the 9th.

The patient was admitted into the Victoria Hospital, Folkestone, on March 9th, and was then constantly sick, the vomit being of a coffee-ground nature. There were abdominal distension and constipation. The chest was normal and the temperature was 99·5° F. It was considered advisable to perform laparotomy and this was done the same evening by Mr. Linington. On opening the abdomen a quantity of turbid sanious fluid escaped. The small bowel was congested and on tracing it down as indicated by the increased depth of colour it was found to be slightly fixed on the right iliac fossa; this was freed and about one foot of gangrenous bowel appeared, greatly thickened, black, lustreless, and in parts sloughy. The attached mesentery was in a similar state. Recognising the condition as one of thrombosis the affected part was excised well clear of the gangrene, 22 inches being removed. Murphy's button was used to unite the ends of the bowel, being augmented by Czerny-Lembert sutures. Considerable difficulty ensued with the mesentery owing to its thickened and rotten state which extended back to its spinal attachment. The dead part was removed and the adjacent edges were made to overlap so as to give greater purchase to the sutures than in an edge-to-edge approximation. The abdomen was flushed out with hot sterile water and was sewn up. The operation lasted just over an hour, being lengthened by the difficulty of dealing with so rotten and swollen a mesentery; it was only with great care that the ligatures could be tightened sufficiently to stop the bleeding without cutting through the part included.

FIG. 1.



Illustrates the post mortem specimen reduced to nearly one-half its actual size. A, Aorta, showing atheromatous ulcers. SM, Superior mesenteric artery. B, Healthy bowel. C, Clots in veins. DD, Glass rods, passed through obstructed branches of the artery.

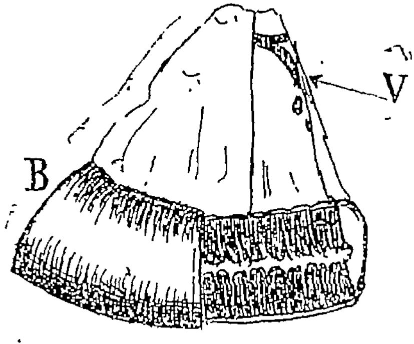
---

[1] Transactions of the Clinical Society of London, vol xxvii, 1894, p. 124.

The patient was very collapsed after the operation but improved somewhat later and was able to retain half an ounce of peptonised milk. She again became worse and notwithstanding the repeated use of stimulants and saline injection death occurred on the 11th, 36 hours after the operation.

Necropsy.—The post-mortem examination revealed atheromatous erosion in the descending aorta and blocking of branches of the superior mesenteric vessels. The Murphy's button was in good position and was watertight. The mesentery was also well secured The part of the bowel excised (22 inches) was from the ileum, one foot from its junction with the cæcum; the greater part of it was gangrenous, the walls being so thickened that the lumen was almost completely obstructed

FIG. 2.



Illustrates the portion removed by operation. Section of mesentery, showing V, clotted vessels. B, Bowel part laid open, showing œdema causing obliteration of lumen

Remarks by DR TYSON and MR LININGTON.—Cases of the above character are comparatively rare and as far as the literature is concerned have been more commonly reported abroad than in England It seems that the general symptoms and signs are almost similar in character, whether the superior or inferior mesenteric artery is involved. Although certain differential points have been given they do not seem to be of much value when practically considered; in both intestinal obstruction is produced and the real cause has rarely been diagnosed or even guessed at before operation or until after death The first prominent symptom is abdominal pain closely resembling an ordinary attack of colic, nausea is frequent and occurs fairly early, and vomiting follows with gradual change in the character of the vomit. Constipation sometimes occurs but diarrhœa has been commonly reported. Tension and tympanitic swelling of the abdomen are late symptoms indicating the advent of peritonitis. Extreme fœtor of the stools is of serious omen and points to gangrene of the bowel. Profuse intestinal hæmorrhage has been recorded and when meeting with this symptom it is as well to bear in mind that embolism of the mesenteric artery may be the cause.

The prognosis is always grave but not absolutely fatal; of course, this must be better if only one branch is involved rather than several—it is doubtful if recovery has ever taken place when the main vessel has been occluded. The greater the arterial obstruction the more severe are the symptoms. As regards the source of the embolus the left heart seems to be the most common and after this the abdominal aorta, as in the present case. The occurrence of thrombosis from injury has also been placed on record. There have been a few cases of thrombosis of the vein only giving rise to intestinal obstruction although the artery was unaffected—notably Fagge's and Bradford's cases. Where the swelling of the bowel from infarcts has occurred the tumour has been mistaken for one of malignant nature.

As regards treatment early abdominal section gives the only possible chance. We have not been able to find any recorded instance of recovery after delayed operation and it is quite conceivable that if the foregoing case had been operated on a few days earlier the result might have been successful It is quite evident that kneading the abdomen in such cases must be absolutely wrong and also that opium in other than minute doses would mask and obscure the real cause of the trouble. No doubt there are slight cases in which the patients get quite well without the cause of the illness being recognised, the symptoms being colic and intestinal hæmorrhage. In these the anastomoses of the vessels along the edge of the mesentery are sufficient to re-establish the circulation through the affected area, thus preventing obstruction and subsequent gangrene; in more severe cases these ensue, because the blood-supply from adjacent vessels is not adequate to the larger area involved.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Discussion on Endotheliomata occurring in Various Regions and their Mode of Origin — Congenital Multiple Sarcoma of the Skin

A MEETING of the section of Pathological Anatomy and Histology of this society was held on April 29th, Dr. J. F. PAYNE, the chairman of the section, being in the chair.

Mr. RAYMOND JOHNSON and Mr. T. W. P. LAWRENCE commenced the Discussion on the Endotheliomata by a paper (illustrated by lantern slides) on a series of specimens of endotheliomata of the salivary gland. The paper was brought forward as a contribution towards the solution of the question as to whether the so-called "parotid tumour" and others of identical structure were to be regarded as of epithelial or connective-tissue origin. Typical encapsuled parotid tumours and similar growths in the neighbourhood had been examined. In none of the specimens in the museum of University College could they satisfy themselves that there existed any adenomatous structure. From their observations Mr. Johnson and Mr Lawrence were in agreement with Rudolf Volkmann and other pathologists who regarded the tumours in question as of connective tissue origin—they were, in fact, endotheliomata. No data were obtainable as to whether they arose in the endothelium of blood-vessels or of the lymphatics. The substitution of the connective tissue for the glandular theory of the nature of the salivary-gland tumours introduced the difficult question of their limited and well-defined distribution. Tumours of the so-called "carotid gland" of identical structure had been met with, and it was suggested that similar vascular formations might occur in other parts of the area of distribution of the carotid vessels from which the tumours in question arose.

Mr. C. G. SELIGMANN read a paper on three cases of Tumour which he regarded as Endotheliomata. Two of these occurred in the soft palate in patients aged 56 and 43 years respectively. In neither of these were there any enlarged glands or other signs of metastasis. The third case was one of abdominal tumour in a woman, aged 31 years.

Dr. H. D ROLLESTON and Dr. O F. F. GRÜNBAUM showed Microscopic Sections from Four Tumours (three from the cheek and one from the lip) belonging to the class of endothelioma. One was a typical endothelioma arising from the endothelium lining lymphatic capillaries; the vessels could be seen undergoing dilatation and distension with proliferated endothelial cells. It appeared probable that the dilatation was due to proliferation of the cells in four directions on the same plane. Alveolar spaces resembling gland tubes were formed in two ways—(1) by degeneration of the cells in an originally solid mass of endothelial cells; and (2) by portions of the connective-tissue basis becoming surrounded by cells and then undergoing degeneration. The acid orcein stain showed elastic tissue in some of the alveoli. The second specimen was a perithelioma, derived from proliferation of the endothelial cells of the perivascular space, and it presented an appearance resembling a villous carcinoma. It illustrated the group of tumours called "blastoma" by Powell White, in which the cells, originally all of one type or "indifferent," eventually formed both epithelial and sarcomatous cells; such tumours had been termed "carcino-sarcoma." The third and fourth specimens, from the lip and cheek respectively, very closely resembled the endotheliomata of the parotid and, like them, contained cartilage.

Mr. A. W. Nuthall and Dr. J. G. Emanuel (Birmingham) read a paper on, and exhibited specimens from, four cases of New Growth affecting the Alimentary Tract and presenting unusual characters, occurring in patients aged 44, 27, 56, and 38 years respectively. In every case the mucous membrane was intact and the serous coat was unaffected, and Mr. Nuthall and Dr. Emanuel advanced reasons for concluding that the growths had not arisen from the mucosa of the bowel but that they were of an endotheliomatous type.

Mr. E. M. Corner and Mr. S. G. Scott showed sections of, and described, a Tumour of the Lip and another one of the Submaxillary Gland, both of long standing and benign. Both shelled out easily and had a fibrous capsule. The structure of the tumour from the lip, which contained islands of cartilage, was fully described. The submaxillary tumour was similar, only it had little or no cartilage. Mr. Corner and Mr. Scott concluded that these tumours had originated from blood-vessel endothelium from the following facts: the structure of the walls of the canals, their lining cells being continuous with those of the parenchyma, their containing blood, and the absence of ordinary blood-vessels in the tumours.

Mr. S. G. Shattock discussed the nature of a Mixed Tumour of Endotheliomatous Type which had occurred upon the lower lip. It was an encapsulated tumour consisting of cartilage, and blood-channels lined with layers of polymorphous epithelium, in place of marked columnar form. The specimen had long been in the museum of University College and he was able to show it through the kindness of Mr. Lawrence. It belonged to the same group as those of the parotid, submaxillary glands, and palate. The cartilage in these tumours he had once thought might indicate a reversion to a tissue found in the glands of the mouth in lower ancestral forms. For besides the atavism which concerned the grosser forms of organs an atavism of tissue—a teleplasia as it might be called—was theoretically possible. He had found no evidence of this; his examination of the parotid gland of the echidna and ornithorhynchus, the most likely of mammalian forms to exhibit such modified structure, showed a stroma of common connective tissue only supporting the acino-tabular elements of the gland. There was no alternative except to connect the cartilage in this series of tumours with Meckel's cartilage, in the proximity of which they occurred, near its exterior termination The blood-channels of the tumour, lined in part with columnar cells, offered great difficulties. In no member of the whole animal series were the blood- or lymph-vessels furnished with columnar epithelium. If the endothelium of the heart and great arteries was derived from the hypoblast or endoderm, the peripheral blood-system arose from vasifactive mesoblastic cells. One suggestion the speaker would make was that the channels might arise in connexion with remnants of certain extensions of the primitive *cœlom.* The pleuro-peritoneal or body cavity or cœlom arose as a direct extension of the primitive alimentary canal—i.e., it was of hypoblastic or endodermal origin. In the dogfish tubular extensions of the cœlom, lined with columnar cells, lay in the substance of the branchial bars, the blood space, lined with flat cells, being alongside; these cœlomic extensions in the dogfish disappeared. Was the system of channels in these tumours related to remnants of cœlomic extensions in the branchial bars, the blood capillaries afterwards coming to communicate with them? or did blood-vessels become invaginated into such a system after the manner described by Professor Ray Lankester as "phleboedesis," the columnar cells of channels in the tumour being furnished by the endodermal cells answering to a lymphatic sheath? Or was it simpler to assume that the mesoblastic cells which gave rise to the capillaries were of endodermal descent and that in these tumours the columnar form was a reversion indicating their primary source?

Mr. G. E. Gask exhibited sections of a Complex Papillomatous Growth consisting of a delicate fibrous stroma and lined by a layer of flattened cubical cells taken from the synovial sheath of the tibialis anticus tendon, subsequent to an injury to the ankle-joint and probably originating from the endothelial lining of the synovial sheath.

Dr. J. F. Payne, in discussing the series of papers which had been brought before the society, thought that the subject was surrounded by a good deal of difficulty. As regards "parotid tumours" he inclined to the view that they originated in some way in embryonal "rests."—Dr. H. Morley Fletcher asked Dr. Rolleston how he accounted for the elastic fibres in the tumour which he had observed, and Dr. Rolleston replied that the elastic fibres had remained while the fibrous tissue around them had undergone degeneration.—Dr. Arthur Whitfield also remarked that this same survival occurred in the lesions of tuberculosis.—Mr. J. H. Targett regarded the specimens exhibited by Mr Nuthall and Dr. Emanuel as examples of schirrhus such as occurred in the stomach. He did not see why these specimens should not be regarded as ordinary carcinomata of the scirrhus type. He had seen a great many tumours of the so-called "parotid" kind occurring in many curious places—the tip of the nose, the lacrymal gland, the palate, parotid gland, and elsewhere—but he had never met with or heard of any occurring away from the face. As regards their origin, he preferred the old-fashioned view—viz., that they were altered gland tissue. At any rate, he felt sure that he could produce sections from them which could not be distinguished from gland tissue.—Mr. J. H. Parsons, Dr. F. J. Poynton, and Mr. J. W. T. Walker also took part in the discussion and Mr. Raymond Johnson replied.

Mr. George Pernet read a paper on a case of Congenital Multiple Sarcoma of the Skin occurring in the body of a newly-born female child which was brought to University College Hospital after death. There were 70 growths disseminated over the skin and sections of some of these revealed the structure of round-cell sarcoma.

Mr. W. G. Spencer exhibited card specimens of (1) Fibromyoma in one Breast and Carcinoma in the other; (2) Hæmorrhagic Cyst of the Pancreas resulting from aseptic hæmorrhagic pancreatitis; and (3) Lymphangioma Hypertrophicum of Congenital Origin.

Mr. W. Watkins-Pitchford (Birmingham) exhibited card specimens of a large Multilocular Cyst of the Pancreas from the body of a woman 29 years of age.

CLINICAL SOCIETY OF LONDON.

Clinical Evening: Exhibition of Cases.

A meeting of this society was held on April 25th, Mr. Howard Marsh, the President, being in the chair.

Mr. H. L. Barnard exhibited: 1. A case of Left Parietal Meningocele or Cephalhydrocele occurring in a male child, aged two weeks, who was brought to the London Hospital for a swelling on his head. The swelling was noticed two days after birth and had not increased in size. It was situated on the upper and posterior part of the left parietal bone and was distinct from the anterior and posterior fontanelles and the sagittal suture. An attempt to reduce it had led to cessation of respiration and pallor. 2. A case of Multiple Chondromata or Osteomata with Synostosis of the Lower Epiphyses of both Ulnæ and Fibulæ. The tumours projected from the ribs, scapulæ, clavicles, and femora, &c. The epiphyses were for the most part enlarged. The lower epiphysis of the ulna had undergone early synostosis on both sides, leading to ulnar displacement of the hand at the wrist-joint. The fibulæ (the homologous bones in the leg) were in the same condition. The patient suffered from severe rickets when a child. 3. A case of Tumour of the Abdominal Wall.

Mr. Hastings Gilford (Reading) showed a case of Conspicuous Delay of Growth and Development. The patient was an instance of a disorder which had not hitherto been systematically described, though some dozen or more cases had been recorded by French and German writers. He was 28 years of age and came of a healthy family. At 23 years of age he was 1·078 metres (three feet six inches) in height and had since grown 18 millimetres. His height and proportions resembled those of a boy between six and seven years of age. A radiogram of the hand showed that ossification was no farther advanced than was usual at the age of 10 years, while the dentition was like that of a child of the same age. The contour of the body and the appearance of the head and face were childish. The sexual organs were the most backward in development; the testes had not descended and the external genitals were infantile. The intelligence was good; but his behaviour and conversation were more like those of a child than of an adult. The thyroid gland could be felt. The dwarfism in this case was apparently not due to any of the known causes of that condition. Achondroplasia, rickets, and microcephaly could be definitely excluded.

Mr. A. A. Bowlby exhibited a case of Ethmoidal Mucocele occurring in a man, aged 26 years, a horsekeeper.

When five years old he had suffered from "an abscess in the left eye," presumably from the history referring to a swelling in the orbit above the inner canthus and closely adherent to the inner wall. This condition had lasted for 13 months and was followed by a persistent painless swelling in the region of the upper part of the nose on the left side On March 10th, 1902, he first noticed that he was unable to breathe through his left nostril and he experienced pain at the inner side of his left eye. Since then the swelling had increased, become more tender, and was accompanied by greater pain. He had never had headache vomiting, or diplopia. Mr Bowlby explained that the inferior and middle turbinate bones had been removed The patient's temperature had been elevated and he had had severe attacks of pain. The vision was perfectly normal, although the eyeball was so displaced. It might be necessary to remove the ethmoid.—Dr HERBERT TILLEY thought that in view of the difficulties connected with the rapid healing of the wound caused by an external operation it would be advisable to operate through the nose by means of sharp spoons, if due caution were used there *should be no danger of encroaching upon the cribriform* plate. Failing relief by this means he would suggest that the ethmoid should be attached by way of a large opening in the anterior wall of the corresponding antrum. By this route the lateral masses of the ethmoid could be reached and easily dealt with

Dr W ESSEX WYNTER exhibited a case of Congenital Absence of the Nose and Anterior Nares, with Deficiency of the Hard and Soft Palate The patient, a female, six weeks old, the first child of healthy parents showed this very unusual deformity without "hare-lip" or deficiency of the premaxilla. The child suffered from difficulty in feeding and respiration. —The PRESIDENT remarked that the case was exceedingly rare. He did not know of any recorded cases.—Dr TILLEY said that on closely examining the case it would be found that the hard palate was not cleft but that its central portion for about one inch in the antero posterior direction and half an inch transversely was abruptly drawn upwards into a smooth concavity No intra nasal structures were visible through the mouth and the soft palate was quite a normal one and continuous with the concavity afore-mentioned

Sir HUGH BEEVOR exhibited a case of Probable Congenital Atelectasis occurring in a single woman, aged 22 years She had no symptoms The heart was on the right side, the apex was in the third interspace in the axilla. The lung appeared to have the upper lobe almost solid, but the bronchi were not patent, the breath sounds being almost absent There was no history of previous illness. A high and narrow palate, a double coloboma of the iris, and developmental changes visible in the lens and retinæ, suggested that the case might be one of congenital atelectasis of the lung or apneumatosis —Dr PERCY KIDD concurred in the diagnosis of collapse of one lobe He had met with such a case in the post-mortem room. He agreed that this case was one of congenital absence of development of the right upper lobe.—Sir H. BEEVOR, in reply, said that he had not been able to meet with any precedent until that mentioned by Dr Kidd, but he had met with early obliteration of the upper lobe.

Mr W G SPENCER *exhibited a case in which Excision of* the Right Wrist by a Posterior Median Incision for Tuberculous Disease had been done three years previously In March, 1900 some sinuses in the right forearm had been scraped and arthrectomy of the left knee performed. Since that time the patient had remained in good health.

Dr J WALTER CARR exhibited a case of Congenital Morbus Cordis with Extreme Clubbing of the Fingers and Toes occurring in a female aged 10 years The child had always suffered from cyanosis and much dyspnœa on exertion *She was fairly well developed and well nourished but showed* a high degree of cyanosis. Clubbing of the finger-ends was marked. The heart was enlarged transversely, mainly to the right, but the exact nature of the lesion was obscure, as the only murmur heard was a very faint systolic one over the left border of the sternum most distinct at the inner end of the second and third spaces There was marked concentration of the blood showing 8 000 000 corpuscles per cubic millimetre and 20 per cent. of hæmoglobin —Dr C H. [illegible] referred to a similar case occurring in a child, aged eight years, who died from *hæmoptysis It resembled the case* exhibited in the almost complete absence of murmur —Dr H. A. CALEY regarded the case as one of deficient interventricular septum, associated probably with pulmonary stenosis

Dr PERCY KIDD exhibited a case of Arthropathy occurring in a case of bronchiectasis. The patient was a man, aged 30 years, a compositor, with enlargement of both hands (including wrist-joints and fingers), ankles, and to a less extent the knees. The fingers and toes were clubbed. The physical signs in the chest resembled those of tuberculosis of the right upper and lower lobes, but no tubercle bacilli could be found in the sputum. The paroxysmal character of the cough and profuse expectoration suggested bronchiectasis The sputum was not offensive. The patient had suffered from gout several times during the past six years and had had chronic cough with expectoration for three years

Mr. A. BEVAN (introduced by Dr ARCHIBALD GARROD) exhibited a case of Urticaria Pigmentosa occurring in a child, five years old. The spots had appeared first upon the legs when she was only two or three months old, at first pink in colour, then gradually turning brown.

Dr STCLAIR THOMSON exhibited a case of Chancriform Ulcer of the Tonsil or "Vincent's Angina." The patient, a boy, aged 12 years, had only been complaining of *a little sore throat for four days The right tonsil* was seen to be occupied by an oblong greyish slough made up of a pulpy or chalky membrane which was easily detached The case was shown as illustrating an uncommon form of membranous ulceration of the tonsil which had been described on the continent under various names, such as "diphtheroid angina," "membranous amygdalitis," and "ulcerating lacunar tonsillitis. The name "angina of Vincent" was given to it in consequence of the discovery by Vincent in the membrane of a spindle shaped bacillus of 4 μ in length and 1 μ in width He had previously discovered the same bacillus in the dirt of hospitals.[1]—Dr HERBERT TILLEY suggested that a careful examination be made of the organisms associated with the ulcer, for in a genuine case of 'ulcerative tonsillitis' their form and arrangement were very characteristic. The affection was usually found in anæmic females.

HARVEIAN SOCIETY OF LONDON

Exhibition of Cases —Tuberculous Disease of the Knee-joint — Idiopathic Hereditary and Family Hæmaturia

A CLINICAL meeting of this society was held on April 24th, Mr W WATSON CHEYNE, the President, being in the chair

Dr T D SAVILL showed a woman aged 39 years, who was the subject of Erythromelalgia or Sclerodactylia. She had had a general eczema of the hands which started 15 months ago The skin was now cured of any eczematous element, but there was left a sclerotic condition which for some months had prevented proper movement of the fingers The redness was almost limited to the digits. All her other skin was healthy There was a history of numb dead hands much the same as in cases of Raynaud's disease. She could not resume her occupation because she was unable to close her hands. The fingers were tapered in the way usually observed in circulatory disorders.—Dr LEONARD G GUTHRIE and Mr F JAFFREY took part in the discussion

Dr ALEXANDER MORISON showed an infant seven months old, who exhibited a great Enlargement of Veins passing from the vertex of the head to the left ear When the child was quiet a venous pulsation could be detected. There was some tension of the fontanelle. Nothing wrong was noticed until the child was three months old It was the third child of the family the first having aborted at five months and the second child was now four years of age A French physician had published a description of the condition, recounting 50 cases, and he stated that there was a specific history in all the cases The French author thought that such children eventually got well. Dr Morison thought that the specific character of the condition was not made out The present patient had been treated for syphilis and for rickets.—Dr E CAUTLEY had seen cases without such history where there was marked obstruction to the circulation In one case of great obstruction the child developed hydrocephalus and the obstruction was found to be due to a tumour Assuming the syphilitic causation of the disease what was the lesion which would produce such a dystrophy? The unilateral condition sometimes met with might be due to the fact that th contained some cystic portions. The growths were carcinomatous. Malignant deposits were seen on the intestines, the omentum, and the liver. The patient was much relieved of her symptoms but she died about three months later. 2. A married woman suffered from pelvic pain and much dyspepsia which did not yield to medical treatment. The menses had become more profuse and frequent recently. A solid ovarian tumour was diagnosed. On opening the abdomen some clear ascitic fluid escaped and a large solid ovarian tumour was removed from the right side and a smaller growth of similar nature from the left side. The larger growth presented a cyst of about the size of an orange at one part. The microscopical sections which were also exhibited showed the growths to be true fibroma.—Dr. WALTER and Mr. STANMORE BISHOP discussed the cases and Dr. GEMMELL replied.

---

[1] Vincent: Annales de l'Institut Pasteur, 1896 p. 488.

Dr. J. LLOYD ROBERTS described a case of death from Uræmia after Ovariotomy. A patient, aged 58 years, a multipara, was found to have a large ovarian tumour extending to about three inches above the umbilicus. There was a considerable cloud of albumin in the urine. The patient was kept under treatment by diet and medicine until the urine contained a mere trace of albumin. Abdominal section was performed and an ordinary multilocular ovarian tumour on the left side was removed. After operation the quantity of urine decreased and the albumin increased again. The patient became restless and sleepless and vomited frequently. Death from uræmic coma took place on the tenth day, only eight ounces of urine loaded with albumin having been passed during the last 48 hours of life. There were no signs of septicæmia or of peritonitis. Post mortem there was double nephritis, the other organs being healthy. The case demonstrated the gravity of the risk in performing major operations in cases of renal degeneration.—The case was discussed by Dr. DONALD and Dr. SINCLAIR and Dr. LLOYD ROBERTS replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Gastric Ulcer.

A MEETING of this section was held on April 11th, Sir CHRISTOPHER NIXON, the President, being in the chair.

Mr. R. F. TOBIN read a paper on Some Medical Aspects of Four Consecutive Cases of Perforated Gastric Ulcer successfully operated on in St. Vincent's Hospital, Dublin. Three of the patients were young domestic servants. In all the cases the position of the ulcer was the same—namely, an inch or two in front of the œsophageal opening. This, he said, was the most common site for perforation. He believed that perforation was the penalty which the overworked anæmic class that furnished most cases paid for being obliged to carry themselves upright from early rising to late bed-time. The liver in such patients was not braced up owing to the laxity of their tissues and to their being on their legs all day long. The stomach, owing to its fixity to the diaphragm, was being continually drawn through a long range of movement in the breathing that was induced by journeys up and down stairs. Now, given congestion of the area under consideration, that which extended from the œsophagus under the liver, it was easy to understand how the pressure and movement referred to would in anæmic subjects cause congestion to pass to ulceration and ulceration to sloughing; also, how rest in the recumbent position was such a healing force in such cases. He referred to the disastrous effects of movement in cases of perforation and laid down the rule that the surgeon should be called to the patient and that no patient should be moved till the opening had been closed. The convenience of operating in hospital did not cover the loss from transportation. He narrated a case on which he operated successfully with the rudest appliances. Shock should not prevent the immediate performance of an operation. It was not mere nervous shock where nothing harmful was going on while the surgeon was waiting for the patient to come round, but, on the contrary, changes were going on that might lead to thrombosis of the mesenteric veins and render operation useless. As regards prevention, he pointed out that sufferers of the servant class were constantly advised to rest in the intervals at work, although in most houses, short of rest in bed, there were no means of enabling them properly to carry out the suggestion offered.

Dr. REDMOND thought that the great difficulty in such cases was the diagnosis of perforation; there might be little or no shock. In one of his cases he found the patient sitting in bed leaning forward supported by two friends and crying out with pain. She had been in excellent health all day and had eaten heartily of mutton at dinner. There was no diminution of the area of liver dulness. He recommended operation; a perforation at the cardiac extremity of the stomach was found and sutured and the patient made a good recovery.

Dr. J. M. FINNY looked on the diagnosis of the perforation as the real difficulty in these cases. One of his patients who had all the typical symptoms of perforation—vomiting, tympany, pain, and so forth—was operated on three hours after the onset of the attack and all the viscera were found to be healthy; there was no ulcer whatever. The abdomen was stitched up and the patient made a good recovery. He had seen a good many operations for perforating ulcer of the stomach and he could not agree that it was so easy a performance as some thought, particularly if the perforation occurred on the posterior wall; such an operation could not be successfully carried out with lamp or candle light. Absence of liver dulness was not an essential symptom in the early stage of the disease.

Dr. J. F. O'CARROL expressed the opinion that the sooner the operation was performed after the perforation the better. Some few cases might recover under medical treatment, but he thought that the safer practice was operation. The onset of shock was the call for laparotomy; interference should never be postponed on account of shock.

Mr. H. G. CROLY, Mr. D. KENNEDY, Dr. JAMES LITTLE, and others also discussed the paper.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.—A meeting of this society was held on April 18th, Dr. Leonard Guthrie being in the chair.—Dr. D. Mackenzie showed a case of Cystic Hygroma of the Neck undergoing spontaneous cure in a child, aged 11 months. It was of the size of a small orange at birth but had become so small as to be scarcely perceptible.—Mr. R. H. A. Whitelocke (Oxford) remarked that Mr. Bland-Sutton had said that these tumours generally disappeared after puberty, but he had seen a case as late as the age of 27 years.—Dr. Edmund Cautley showed a case of the Peroneal Type of Muscular Atrophy in a girl, aged seven years. She was the third of five living children. There was no history of similar atrophy of muscles or of nervous disorders in the family except epilepsy in a brother and a sister of the mother. The child showed a "claw-like" deformity of the hand due to paralysis and atrophy of all the intrinsic muscles and "club foot" due to atrophy of the corresponding muscles of the foot and of the peronei and extensors of the toes. The other muscles below the knees, the vasti interni, and to a less extent the hamstrings, tensor vaginæ femoris, and glutei were also involved. The affection began in early life and was perhaps secondary to measles at the age of six months.—Dr. Guthrie, Dr. Fletcher Beach, Mr. H. J. Curtis, Dr. Dawson Williams, and Dr. G. A. Sutherland discussed the paper.—Mr. Sydney Stephenson showed a child, aged eight years, who presented Tuberculosis of the Choroid in the Right Eye and slight signs of phthisis at the apex of the left lung. He knew a case of tubercle of the choroid which had apparently dated back for 30 years.—Dr. Guthrie, Dr. George Carpenter, and Mr. Curtis took part in the discussion.—Dr. J. W. Thomson Walker showed a Tuberculous Nodule of the size of a walnut arising from the dura mater and embedded in the upper and inner part of the left cerebellar hemisphere. Death was due to meningitis, cultures from which showed staphylococci.—Dr. Walker also showed a Primary Osteoma of the Floor of the Third Ventricle with the Formation of a Cyst at one part. The symptoms were those of left cerebellar disease and an exploratory operation had been performed. Only 11 other examples of the tumour were found in literature.—Dr. Guthrie remarked upon the misleading symptoms which had shown themselves in the second case. The girl had right-sided headache and kept her head turned to the right side. Double optic neuritis, slight right facial paralysis, and tremors of the right arm were present, and the right knee-jerk was exaggerated. When placed upon her feet she reeled towards the right. The right side of the cerebellum was, however, found to be quite healthy.—Dr. Sutherland, Mr. Edmunds, Dr. Theodore Fisher, (Bristol), and Dr. Burgess discussed the cases.—Mr. Whitelocke read notes of the case of a girl, aged four years, who was admitted to the Radcliffe Infirmary, Oxford, for supposed Strangulated Left Inguinal Hernia. A reducible hernia was also present on the right side. Double herniotomy was performed and from the left side a body was removed which bore some resemblance to an ovary. A similar body was present on the right side, but it was returned to the abdomen. On microscopic examination the body removed proved to be a testis. Photographs of the external genitalia were shown illustrating the fact that to all appearances they were those of a normal female child.—Dr. Sutherland remarked upon the difficulty of deciding as to the way in which the child should be brought up, whether as a boy or as a girl.—Dr. Guthrie agreed with Dr Sutherland that she should be brought up as a girl.—Mr. Whitelocke, in reply, said the question of sex was a difficult one. He had heard of a case where a hermaphrodite, if considered a male, was entitled to considerable property.—Dr. C. O. Hawthorne and Mr. Curtis read a paper on a case of Transperitoneal Nephrectomy for Small Round-celled Sarcoma, the patient being a boy, aged four years. The tumour removed weighed three pounds 15 ounces. It appeared to have commenced on the hilum of the left kidney. The wound healed and the stitches were removed. Death, however, occurred on the fifteenth day after the operation from extensive bilateral pleurisy with effusion. No secondary growths could be discovered at the necropsy and no trace of peritonitis or of suppuration elsewhere. The need for early diagnosis and immediate operation in carefully selected cases was emphasised and successful results were quoted.—Dr. D. N. Nabarro, Dr. J. Porter Parkinson, and Dr. Fisher discussed the case.—Dr. Carpenter read notes of a case of Malignant Endocarditis in a boy, aged eight years. Intense optic papillitis supervened associated with simulated choroidal tubercle and sub-retinal hæmorrhages. Just before death embolism of the right common iliac artery occurred.

HUNTERIAN SOCIETY.—A clinical meeting of this society was held on April 9th, Dr. A. L. Galabin, the President, being in the chair.—Dr. F. J. Smith showed a case of Lymphadenoma in a girl, aged eight years, who was admitted to the London Hospital in February, 1902, under the care of Dr. A. E. Sansom. She had had whooping-cough, chicken-pox, and measles, the last named at the age of four years, and it was subsequently to this illness that a lump was noticed in the left side of the neck which had increased in size in an irregular manner. She was a fairly healthy-looking child, apparently enjoying pretty good general health except for some shortness of breath and cough on exertion. Examination of her blood showed 4,000,000 red corpuscles and 4000 white corpuscles per cubic millimetre. Her digestive system seemed to be quite healthy but the spleen was easily to be felt extending some three inches or so below the costal margin. Some slight irregularity was occasionally present in the heart's rhythm and a hæmic bruit was to be heard when she lay down; the frequency of the pulse was also above the average, varying between 100 and 120 per minute. There was increased resistance on percussion over the upper part of the left chest, but air entered both lungs freely and without any adventitious sounds. The urinary and nervous systems were without obvious abnormality. Her temperature occasionally rose to 100°F but was usually normal or slightly subnormal. A swelling of about the size of a man's closed fist was visible in the left side of her neck, with slight thickening of the tissues of the upper arm and pectoral region, though there was no pitting on pressure. To the hand the lump evidently consisted of enlarged cervical glands; the skin was freely moveable over them and they were freely moveable amongst the deep connective tissue. The individual glands were easily to be felt without any matting together of glands and connective tissue. No other glands were enlarged. The patient had been treated during her stay in hospital with arsenic in increasing doses up to six minims of Fowler's solution per diem and with extract of malt, and under this she had gained in weight 10 pounds in six weeks. Dr. Smith preferred to give a preliminary diagnosis of enlargement of lymphatic glands simply. Tubercle, he thought, could be eliminated by the absence of adhesions of the glands to one another or to the skin after a duration of four years. The duration of the case excluded any process that might be called sarcomatous and he was driven to conclude that the patient was the victim of a disease which would ultimately destroy life unless arsenic were able to hold it in check. He thought that one or other of the glands might be removed with a view to making the diagnosis more certain, as it was possibly a case of splenic anæmia in a child with some tuberculous glands.—Dr. Smith also showed a case of Hemiplegia in a boy, aged nine years. About six or seven months ago, when he was over eight years old, he began to lose power in the right arm and leg. There was now great weakness of all the muscles of the right hand and arm to the shoulder, also of the right leg to the thigh, accompanied by complete freedom of movement on the left side. The perception of general sensation and its localisation were fairly good over the affected areas (quite good over the non-affected ones) but he had very defective judgment between heat and cold all down the right side, the arm, the trunk, and the leg. The patellar reflex on both sides was above the average, but on the right side it was very exaggerated and was accompanied by ankle clonus; on tickling the soles the right big toe was bent up (pathological) while the left one was bent down (normal). The cranial nerves seemed to be quite healthy. Intelligence was unimpaired and the patient had no peculiarities of speech and no headaches. Dr. Smith's diagnosis was degeneration of nerve fibres; the evidence, especially the spasticity, was on the whole in favour of a cortical lesion.—Dr. W. H. Kelson showed a case of Enlargement of the Right and Middle Lobes of the Thyroid Body of six years' duration in a woman, aged 33 years. Slight tremor and palpitation were present and she suffered from menstrual irregularity and breathlessness. Dr. Kelson took the view that the symptoms were due to some abnormality in the thyroid secretion and that in very varying degree such symptoms were always present in all thyroid enlargements, the culminating point being a typical case of exophthalmic goitre, although microscopically the appearances differed considerably.—Sir Hugh R. Beevor showed a case of Factitious Urticaria.—Dr. David Ross showed a case of Tetany in a labourer.—Dr Kelson, Dr. T. Glover Lyon, Dr. Milligan, Sir Hugh Beevor, Mr. J. H. Targett, and the President discussed the cases.

CHELSEA CLINICAL SOCIETY.—A meeting of this society was held on April 15th, Dr. C. A. Morris, C.V.O., the President, being in the chair.—Dr. C. C. Gibbes showed a case of Patency of the Ductus Arteriosus occurring in a man, 27 years of age, pale in complexion, stunted in growth, and badly developed. Dyspnœa, œdema, cyanosis, and clubbing of the finger-tips were entirely absent. The heart was normal in size. A systolic murmur could be heard over the right carotid artery and in the aortic area but there was no diastolic murmur. A continuous harsh murmur, commencing about the middle of the systole, running through the second sound, and occupying about two-thirds of the diastole could be heard over the whole of the first, second, and third intercostal spaces. It could not be heard over the sternum. There was no thrill.—Dr. T. Vincent Dickinson read the notes of a case illustrating the value of Belladonna in the treatment of Broncho-pneumonia in children. The patient, a girl of good physique, aged nine years, was attacked with typical broncho-pneumonia following measles. One-quarter of a grain of extract of belladonna rubbed up with glycerine and chloroform water was administered every four hours and three days afterwards the dose was increased to three-eighths of a grain every two hours, and one hundredth of a grain of digitalin and one-sixtieth of a grain of strychnine were injected. Improvement was noted the following day, and the belladonna was reduced to one-quarter of a grain. From this stage improvement continued rapidly to convalescence.—The President read notes of a case of Hydramnios in the fifth month of pregnancy. The patient, who was 37 years of age and married, had five children, the last being one year and ten months old. The abdomen appeared to be larger than in former pregnancies of the same date and it was now found to be much distended by a tumour reaching up to the ensiform cartilage which was dull on percussion and gave throughout a very distinct and superficial feeling of fluid. Per vaginam the cervix was found to be soft and the os was dilated so as to admit the finger; ballottement was easily obtained; and the membranes were bulging into the cervical canal. Hydramnios was diagnosed. Under ether the os was gradually dilated with the finger until all the fingers could be introduced; the membranes were ruptured and the fluid was allowed to escape very gradually the hand being used occasionally to close the canal. Two children were delivered by turning, perforation of the skull being necessary. Altogether ten pints of amniotic fluid were collected. The placenta came away easily by expression, with no post-partum hæmorrhage. There was a single placenta with two amniotic cavities. The patient made an uninterrupted recovery. The history in this case was fairly typical. A multipara has a normal pregnancy up to the fourth or fifth month when the abdomen enlarges rapidly and causes extreme distress from pressure. The case usually ends in abortion before the end of the seventh month. The condition is very common in twin pregnancies. The causes of the condition are doubtful. The symptoms resemble those of pregnancy complicated by an ovarian cyst, and the chief sign as an aid to diagnosis consists in the intermittent contractions of the uterine walls, which were very distinctly felt in this case and affected all parts of the tumour. The treatment here adopted was correct, as limited aspiration had been tried and had failed and drugs were useless. The children very seldom survive for many hours.

EPIDEMIOLOGICAL SOCIETY.—At a meeting of this society held on April 18th, Dr. Patrick Manson, C.M.G., the President, being in the chair, Dr. J. C. Thresh, medical officer of health of the Essex County Council, read a paper on Small-pox Hospitals and the Spread of Infection which was published in THE LANCET of April 26th, p. 1172.—Dr. A. Newsholme was not convinced by Dr. Thresh's arguments; more or less surreptitious intercourse did take place between the ships and the shore. He would like to have had a complete history of the first dozen or so cases, on which the whole subsequent course of the epidemic might depend. The mere fact of one district suffering more than others was not sufficient, for so did West Ham with no hospital in its vicinity. Dr. Thresh spoke of miles whereas Mr. W. H. Power did not go beyond quarters of miles, and he had referred to *prevailing* winds without saying whether the outbreaks corresponded with changes in the actual direction. He would allow 40 patients in a hospital and had seen no harm result from 100 or 350, though Mr. Power saw a possible danger from nine. The theories of aerial diffusion and the concentration of the poison threatened to reduce the question of hospital provision to an absurdity and an impossibility.—Dr. L. Parkes believed in aerial diffusion up to perhaps a mile and that small-pox behaved differently from other fevers. If, however, they would but adopt the German system of universal vaccination and compulsory revaccination there would be no need for hospitals at all.—Dr. E. W. Goodall pointed out that if Mr. Power's comparison of a hospital to a fire were good the wisdom of piling up all our infective material in one place was very doubtful. He would like to know whether the closure of the small-pox hospitals in London had effected a change in the local incidence of the disease as shown in Mr Power's series of maps since 1860, or whether it still haunted the same localities. The susceptibility of workmen about a hospital to small-pox and fevers was mainly a question of age incidence. Dr. Thresh attached much importance to strong winds as vehicles whereas Mr. Power taught that the infection spread further in calm, foggy weather.—Major W. G. Macpherson said that at Gibraltar in the epidemic of 1893-95 he or his inspectors had visited every case and had been able to trace it to its source in Spain or Africa. Until the publication of Mr. Power's report the cases had been treated in an old building in the very heart of the city and they were afterwards accommodated in one 400 yards outside, but never had he had any evidence of aerial infection. The spread of the disease was invariably the result of delayed notification, home treatment, or concealment of cases, and when a patient had been promptly removed secondary cases were unknown; infant vaccination was strictly enforced.—Dr. S. Richmond, medical officer of health of Dartford, said that of 200 cases in that district 95 patients were employed as workmen or tradesmen about the Gore Farm Hospital, 60 cases at Swanscombe to the windward of the hospital were traced to labourers and others from London, and altogether there were not 40 unaccounted for by ordinary personal contact.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—A meeting of this society was held on April 24th, Dr. A. J. Harrison, the President, being in the chair.—The President announced that as Dr. Unna's oration at the annual meeting would deal with the subject of Eczema it would be interesting if members brought forward carefully selected cases to illustrate the subject.—The President then read notes giving the termination of a case which he reported to the society in February, 1901, with the provisional diagnosis Senile Syphilis. The patient, a man, aged 74 years, had recently developed peculiar looking growths on the thigh. He had suffered from syphilis 50 years previously, but he had shown no further manifestation of the disease and his children were not affected. He improved for a time under iodide of potassium with a mercurial inunction. Gradually, however, his health failed and he died eventually from cardiac failure. The growth proved to be a round-celled sarcoma. There was no evidence clinically of sarcoma of the internal organs. The President considered the probability of this being a case of primary sarcoma of the skin.—Some fine drawings and microscopic specimens illustrating the case were exhibited. The President was asked to allow the former to be reproduced in the Transactions and he gave his consent.—The following cases were shown:—Dr. G. N. Meachen (for Dr. Abraham): 1. A Case for Diagnosis. This was recognised as an instance of the white spot dermatosis described by Dr. Westberg from one of Unna's cases. On the arms were minute white atrophic spots, each surrounded by an extremely narrow erythematous border. This latter sign was not present in Unna's case. 2. A case of Erythema following vaccination in a man who also showed Lichen Planus on the legs. 3. A case of Milium affecting nearly the whole of the face of a baby.—Dr. Edward Stainer showed: (1) A case of Hyperkeratosis of the palms and soles in a girl, aged 15 years, no cause for which could be discovered; and (2) a child showing Multiple Acanthomata on the face and hands.—Dr. Graham Little showed: (1) A baby suffering from Congenital Syphilis complicated by Eczema; and (2) a woman suffering from Syphilis who had developed an intense Iodide Eruption. —Dr. A. Eddowes showed: (1) A case of Healed Lupus treated by complete excision; and (2) a child suffering from Hydroa Vacciniforme. The eruption affected the central part of the face and the back of each hand. It had recurred three years in succession. A microscopic specimen from the case was exhibited at the same time.—Dr. W. Warde (for Dr. Abraham) showed a case of Thrombotic Lupus. The patient, a woman, had 36 years previously had many scrofulous ulcers. All healed save one and that remained infiltrated. One year ago the patient had an attack of erysipelas and some months after the face became covered by an eruption of small lupus nodules.—Mr. G. Pernet showed sections from a case of Yaws stained by Pappenheim's method to demonstrate plasma cells.

WIGAN MEDICAL SOCIETY.—The ordinary meeting of this society was held on April 17th, Mr. T. M. Angior, the President, being in the chair.—The President gave his address on Diphtheria and Its Treatment. He drew comparisons between the definitions of diphtheria of the older text-books and those of to-day. He also compared the treatment of diphtheria in the pre-antitoxin period with that at the present time. This was illustrated by notes on cases which he had attended before 1895 and after that date, showing a high rate of mortality when serum was not used as compared with to-day. He spoke on the advisability of its early use in the disease and of repeating the injections two or three times if necessary. He remarked on one particular case (fatal) where serum was not used until from the seventh to the tenth day of disease, which was too late to be efficacious. He emphasised the necessity of discussion before medical societies of this particular disease, whilst certain authorities recently had been tempted to hold the antitoxin treatment in disfavour. Complications which had been said to arise from the use of serum were touched upon; he (the President) had experienced none. He mentioned the fact of the antitoxin serum having been administered by the mouth and with satisfactory results, and suggested that this might be a preferable mode rather than risk any tendency to tetanus due to puncture in patients with nerve idiosyncrasies.—An interesting discussion followed, in which Mr. J. Chronnell, Mr. W. Latham, Mr. H. Winstanley, Dr. F. Rees, Dr. J. Blair, Mr. Maurice McElligott, and the honorary secretary took part. A consensus of opinion advocated the antitoxin treatment from as early a period as possible and with regard to isolation that at least three weeks should be enforced.—The President replied.—Mr. W. Mitchell Roocroft then read notes on the following cases: (1) Gastro-jejunostomy; (2) Abdominal Hysterectomy; and (3) Nephrolithotomy.—An interesting discussion followed and the following members took part: the President, Dr. Rees, Dr. R. P. White, Mr. C. M. Brady, Dr. E. H. Monks, and Dr. Blair. Mr. Roocroft replied

PLAISTOW AND CANNING TOWN MEDICAL SOCIETY.—A meeting of this society was held on April 24th, Mr Percy Rose being in the chair.—After an exhibition of interesting cases and also of macroscopic and microscopic-pathological specimens Dr. W. J Hadley gave an address on Some Points in the Diagnosis, Prognosis, and Treatment of Pulmonary Tuberculosis. The points emphasised were the necessity for early diagnosis in order to get the best results to treatment and the differential diagnosis between tuberculosis and some other chest and pulmonary affections The methods of diagnosis were from symptoms, signs, and examination of the sputum. Symptoms were generally present and signs not infrequently absent in the early cases. The testing of sputa for bacilli was the only sure test, and whilst positive results to such testing were conclusive negative results could only be relied on after several repetitions. Differential diagnosis was then given between tuberculous disease and (1) bronchitis; (2) pulmonary growth and other intra-thoracic tumours; (3) syphilis; (4) actinomycosis, (5) hydatid; (6) aspergillosis; (7) bronchiectasis, with or without fibroid lung; (8) pulmonary gangrene; and (9) foreign body. Prognosis was influenced by (1) the family history; (2) the occupation; (3) the age; (4) the comparison of the duration of the disease with the progress which it had made; (5) the comparison of constitutional disturbance with the extent of the lesion; and (6) the conditions under which the cure was to be attempted and maintained. The rest of the address was devoted to treatment, which was divided into preventive, general, and the special treatment of symptoms and complications.—A general discussion followed and a number of questions were put to the reader of the paper.—The meeting concluded by a hearty vote of thanks being given to Dr. Hadley for his interesting address.

GLASGOW SOUTHERN MEDICAL SOCIETY.—A meeting of this society was held on April 17th, Dr. John Stewart, the President, being in the chair.—Dr. G. H. Edington showed a patient, a boy, aged 11 years, who was the subject of Coxa Vara. In a short statement the history, the symptoms, and the treatment of this very uncommon complaint were in turn reviewed. Special reference was also made to the differential diagnosis from morbus coxæ.—The committee appointed to draw up a protest against the recent edict of the General Medical Council with reference to the keeping of open shops or "medical halls" and the sale of poisons then gave the result of its deliberations. The following protest was submitted and unanimously approved of by the meeting:—

James Robertson, Esq., Registrar of Scottish Branch of the General Council of Medical Education and Registration of the United Kingdom.

SIR,—We, the undersigned, in name and on behalf of the Glasgow Southern Medical Society, hereby protest against the notice of the General Medical Council to registered medical practitioners published in the *Glasgow Herald* of Dec 14th, 1901, as being unwarrantable, oppressive, and vexatious.

(Signed) JOHN STEWART, President.
DUNCAN MACGILVRAY, Vice-President.
THOMAS FORREST, Treasurer.
JOHN FRASER ORR, Secretary
ANDREW WAUCHOPE, Editorial Secretary
JAMES FORRESTER, } Members.
LACHLAN BURGES, }

PATHOLOGICAL SOCIETY OF MANCHESTER—A meeting of this society was held on April 16th, Dr. J. Collier being in the chair—Mr. F. A. Southam read a paper on a case of *Fat embolism following a Compound Fracture of the Tibia*, due to direct violence, occurring in a man, aged 43 years (*vide* p. 1240 of our present issue)—Dr A. Knyvett Gordon showed a Continuous Suture that had been passed per anum on the tenth day after Laparotomy, and Suture of a Perforation in the lower end of the Ileum, occurring in the second week of a relapse of enteric fever. The patient was a girl, aged eight years, who after the operation went through the remainder of the relapse of enteric fever and made an uneventful recovery The passage of the suture was not attended by any constitutional disturbance. In sewing up the ulcer a continuous suture was used and Dr. Gordon attributed the sloughing that had taken place to the pressure of the silk over the entire area sewn up, stating, however, that he was inclined to prefer the continuous suture on account of the rapidity with which the stitches could be inserted, a most important point in dealing with the lesion of enteric fever In this case the duration of the operation was 20 minutes—Other preparations were exhibited as card specimens.

ERRATUM.—In THE LANCET of April 26th, p. 1182, in the report of Dr. E. E. Glynn's paper read before the Pathological Section of the Liverpool Medical Institution, the words, "In two cases at least cancer appeared to have originated in a previous chronic ulcer," should be, "In two cases it was demonstrated that cancer had originated in a previous chronic ulcer."

Reviews and Notices of Books.

Diseases of the Intestines. By Dr. J. BOAS, Specialist for Gastro-intestinal Diseases in Berlin. Authorised translation from the first German edition, with special additions by SEYMOUR BASCH, M.D. London: Henry Kimpton. 1901. Pp. 562. Price 21s.

THE popularity which Dr. Boas's treatise has enjoyed abroad and the absence of any detailed and exhaustive work on intestinal diseases in English have led to the publication of the present translation. Dr. Basch has performed his task well and has produced an English edition free from the characteristics of German grammatical construction. The book is intended more especially for the requirements of the general practitioner, but containing, as it does, an exhaustive and concise description of physiologico-chemical processes and laboratory methods, it will also prove of value to scientific investigators.

The first two chapters of the book deal with anatomical, histological, physiological, and physiologico-chemical points which must be thoroughly understood before a comprehensive knowledge of the diseases of the intestines can be obtained. The various methods of examining patients are then minutely described. The chapter on Examination of the Fæces is an important one; the microscopical and chemical examinations are considered mainly in regard to the clinical aspects and the diagnostic importance of the various tests is fully discussed. The chapter on Acute and Chronic Intestinal Catarrh contains much useful information and the remarks on treatment well deserve attention, although the dietetic regimen is scarcely that which is usually adopted in this country

The surgeon will find much to interest him in the chapter on Intestinal Neoplasms. A good *résumé* is given of the various operations which have been performed for the removal of the growths and Czerny's extensive statistics are quoted The results are encouraging but the exact figures are too involved to reproduce in a review. The chapter on Intestinal Stenosis and Intestinal Obstruction is also well arranged. The classification introduced by Sir Frederick Treves is adopted but Dr Boas makes many original observations The remarks on Appendicitis will naturally attract attention and the symptoms of that condition will be found accurately and concisely described. The diagnostic and prognostic importance of the temperature in appendicitis is rightly insisted upon and stress is also laid on the characters of the pulse. Severe peritonitis may exist without any rise of the temperature and it is in these cases that the pulse becomes of so much importance; the frequency and regularity (or the reverse) should therefore be constantly noted. The section on Differential Diagnosis is also worthy of notice The indications for operation are fully discussed The views of various observers are duly noted and clear rules are given as to when, in Dr Boas's opinion, the aid of the surgeon should be called in. In operating in cases of chronic appendicitis Dr. Boas considers that the social status and the vocation of the patient are of great importance in deciding for, or against, an operation. In the case of a patient who is so situated that he can take every possible care of himself an operation will probably not be so urgently called for as in one who has to work hard for a living. In relapsing appendicitis, especially among the working classes, operative interference is indicated when the attacks occur at short intervals and become more and more severe. We may direct attention to the chapter on Nervous Diseases of the Intestines. Many affections of common occurrence are there described and numerous valuable hints in regard to treatment are given.

The illustrations throughout the book are good and are well produced. The whole work is an interesting one and will amply repay perusal.

Atlas und Grundriss der Psychiatrie. (Atlas and Manual of Insanity.) Von Privat-dozent Dr. W. WEYGANDT in Würzburg. With 24 coloured Plates by JOH. FINK and W. FREYTAG, and 276 Illustrations. Munich: J. F. Lehmann. 1902. Pp. 663. Price 16 marks.

THIS text-book is the twenty-seventh volume of Lehmann's Medical Atlas and Manual Series. Although a treatise on insanity does not lend itself to illustrations to the same extent as do works on other branches of medicine, nevertheless a great effort has been made to maintain this feature of the series in the present volume and, it must be admitted, with considerable success. An excellent collection of types, for the most part original and taken from photographs by the author, has been reproduced to represent the various forms of mental disease, and many of the cases which are cited to illustrate the text are accompanied by a portrait of the patient, forming together as objective and practical a presentation of the subject as is possible.

The first part of the book takes a general view of the subject. The author commences with a short but clear exposition of the normal psychological processes and then proceeds to demonstrate the abnormal variations to which these are liable. The principles laid down are thoroughly sound and orthodox; in dealing with the abnormal the reader is always carried back to the normal and an endeavour is made to show the different stages by which the one condition may develop from the other. The pathological account is somewhat scanty and strictly anatomical. The author has nothing to tell us about general pathological or psycho-pathological principles or theories. A chapter is devoted to the treatment of the insane, in which the arrangement of model asylums is described with considerable detail, ground plans of the buildings and other details being given. The author advocates the hydropathic treatment, and especially the continuous bath, for many cases and he strongly urges the total exclusion of alcohol from all asylums.

The second part of the book deals with mental diseases *seriatim* and in his clinical classification Dr. Weygandt follows Kraepelin. The descriptions of the diseases are concise and thorough, and in a comparatively small space a clear and lively clinical picture is given of the disease under consideration. Altogether 143 cases are cited to illustrate typical and atypical mental conditions. The chapter on Epilepsy is very interesting and instructive and the author's remarks on the relationship of epilepsy to alcohol are suggestive, especially the opinion here held, as put forward by Kraepelin, that certain forms of dipsomania in which periods of alcoholic excess alternate with intervals of sobriety are epileptic in origin and nature. Although pregnancy and childbirth are, of course, frequently referred to in the text as immediate causes of different forms of insanity, the usual custom of devoting a separate section to this part of the subject is not adhered to. On the question of alcohol Dr. Weygandt is absolutely uncompromising. He cites experiments showing that a man who takes one litre of beer a day, equivalent to 45 grammes of alcohol (about one and a half ounces), thereby reduces his capacity for work and he would stigmatise such a man as a "drinker." He discusses the subject at length in its social aspect and makes an eloquent appeal for more stringent measures against the terrible ravages caused by drink.

On the whole the book is a thoroughly useful manual on the subject with which it deals and a worthy contribution to the series.

A Handbook of Pathological Anatomy and Histology. By FRANCIS DELAFIELD, M.D., Professor of the Practice of Medicine, Columbia University, New York, and T. MITCHELL PRUDDEN, M.D., Professor of Pathology in the same University. Sixth edition. London: Baillière, Tindall, and Cox. 1902. Royal 8vo, pp. xix. and 819. Price 21*s.*

FORMER editions of this handbook have probably been better known in America than in this country. There is good reason for its taking here as prominent a place as a text-book for students as it has long done on its merits there. We gather from the preface that Professor Delafield has retired from an active share in the revision of the work, so that the responsibility for this edition rests mainly with Professor Prudden who has secured the assistance of several able coadjutors in carrying out his task.

The plan of the book is comprehensive. It is divided into three parts, the first dealing with the methods of post-mortem examination and of preserving and examining pathological tissues, the second being devoted to general pathology in which bacteriology takes its due place, and the third, and largest, comprising the special pathology of the different tissues and organs. The first part is short but eminently practical and useful; it describes thoroughly and completely the way in which a body should be examined after death, both from a pathological and a medico-legal standpoint. Special sections are devoted to cases of suspected poisoning and to examination of the bodies of newly-born children, while an adequate account is given of the lesions found in the commoner forms of violent and sudden death. The chapter devoted to Microscopic Technique is necessarily short and makes no pretence at completeness, but it is all to the point and contains a large number of useful hints.

The second part of the book, devoted to general pathology, occupies some 275 pages, but this includes an account of all the important infective diseases. It is too often the case that a writer on general pathology thinks it incumbent upon him to include in his treatise a complete text-book on bacteriology. In this book an admirable restraint has been exercised. Just so much detail has been introduced concerning the form, structure, and physiology of bacteria and other micro-parasites as to render intelligible to the student the part which these organisms play in pathology, but it is all done, and well done, in little more than 30 pages. The only omission which we see reason to regret is a criticism of modern theories of immunity which might well have found place in a work on general pathology. Such criticism has, however, been deemed outside the scope of the book. The various infections are excellently and tersely described, the morbid anatomy and histology of each preceding the account of its special microbe. The different chapters in the second part of the book show some variations in the fulness of their detail. That dealing with Atrophy, Degeneration, and Necrosis appears to us somewhat inadequate—lardaceous disease, for example, being dismissed in little more than a single page. The chapter on Inflammation and the Healing of Wounds is, however, excellent as is also that on Tumours.

The third portion of the work, dealing with special pathology, is naturally the largest, occupying some 430 pages. Even in this space it is obviously impossible to deal with such a subject in anything approaching fulness of detail. Nevertheless the account of the morbid anatomy and histology of the different organs is thoroughly good and excellently adapted for the student. We have tested it as a manual of reference in routine pathological work and have seldom found it wanting in at least a short account of the lesion under consideration. If, indeed, we were asked to name the distinguishing feature of this book we should unhesitatingly mention its admirable perspective. We have had occasion to review in these columns more than one work of similar aims in which too much had been attempted and in which the concise and lucid treatment required by the modern student of medicine in a useful text book was conspicuously absent. Here this is not so and we can recommend the volume most heartily to students and practitioners as a first-rate guide to modern pathology.

Our review would be incomplete without reference to the figures which so profusely illustrate the subject-matter. These include 13 full page plates and no less than 453 illustrations in the text, a good many are in colours. They are clear and artistic and are printed with unusual distinctness owing to the fine character of the paper employed. It is not often that so well illustrated a text book is met with.

Therapeutics its Principles and Practice By HORATIO C. WOOD, M.D, LL.D, Professor of Materia Medica and Therapeutics and Clinical Professor of Diseases of the Nervous System in the University of Pennsylvania, and HORATIO C WOOD jun, M.D, Demonstrator of Pharmacodynamics in the University of Pennsylvania. Eleventh edition. London Smith, Elder, and Co. 1902. Pp. 850 Price 18s.

THE eleventh edition of a work requires, as a rule, but few words from the reviewer. In this instance, however, the original author has been joined by his son and the result has been that the present volume, although retaining many of its old features, is so different from its predecessors as properly to be considered a new book. The principal changes have consisted in making the various articles conform more closely to a uniform and carefully arranged scheme. The descriptions of the general effects produced by drugs in the lower animals, minor theoretical discussions, and other matters of less importance than those considered in the general text have been printed in smaller type. The literary references have been omitted from the body of the text and have been placed at the end of the various chapters. This plan makes the reading of the book pleasanter and the student's attention is not distracted by the constant interpolation of the names of observers and the work or publication from which the reference has been taken. An excellent method is adopted of giving a summary in large type of the action of all the principal drugs. This is most convenient for the purpose of reference and enables the student to systematise his knowledge in such a manner as to be easily retained. For English readers however, the book has one great disadvantage—the preparations of the English Pharmacopœia are not given, consequently although much information may be gained from the work as to the principles of therapeutics, from the point of view of materia medica the volume is of little use.

Forensic Medicine and Toxicology By J DIXON MANN, M D St. And, F R.C.P Lond, Professor of Forensic Medicine and Toxicology in Owens College, Manchester, Examiner in Forensic Medicine in the University of London and in the Victoria University, Physician to the Salford Royal Hospital. Third edition, revised and enlarged London Charles Griffin and Co 1902. Pp 692. Price 21s

THE text of this very excellent work on forensic medicine and toxicology has been thoroughly revised in accordance with the results of recent scientific researches on the subjects of which it treats. The main additions are to be found in Part III. which is concerned with toxicology. The section on Arsenical Poisoning has been re-written, advantage being taken of the observations which were made during the recent outbreak in Lancashire. The remarks on the elimination of arsenic have been considerably amplified, Dr Dixon Mann's own observations being fully incorporated in the general text. He points out that arsenic has been regarded as a non cumulative poison, and when only a few doses are taken this view is correct. "Cumulative however, is a relative term and although arsenic does not appear to combine intimately with the tissues as some of the heavy metals do, still when small doses are taken into the system in close succession for a considerable period as in chronic poisoning, a certain residuum remains in the tissues after the last dose has been taken for a much longer time than was formerly supposed. In one case Dr Dixon Mann found arsenic in tissues examined 52 days after the last dose had been taken. In chronic arsenical poisoning arsenic may be detected over prolonged periods (49 days) in the exfoliated horny scales of the epidermis, in the nails and in the hair. These results are interesting and of considerable practical value. Some additional poisons have been included in this edition, amongst these being digitalin, fly papers, formalin heroin hydrofluoric acid, hyoscine and 'paregoric.' The list of poisons is now very complete and forms a valuable source of reference for the practitioner.

We consider this work to be one of the best text-books on forensic medicine and toxicology now in print and we cordially recommend it to students who are preparing for their examinations and also to practitioners who in the course of their professional work may at any time be called upon to assist in the investigation of a medico legal case.

LIBRARY TABLE

Atlas and Principles of Bacteriology and Text book of Special Bacteriologic Diagnosis By Professor K. B LEHMANN and Dr R. O NEUMANN Authorised translation from the second enlarged and revised German edition Edited by G H. WEAVER, M D, of the Rush Medical College, Chicago. London and Philadelphia W B Saunders and Co 1901 In two vols Atlas, 69 plates, text, 511 pages Price 21s.—It is rather more than two years since we reviewed in these columns the German original of this translation. We were able to speak of it, and especially of its textual part, in terms of high commendation, we have no reason for altering our opinion and, indeed a perusal of this translation only inclines us to emphasise our former verdict. The plates forming the atlas are as good as can be expected in the case of inexpensive coloured figures and are of undoubted utility. Professor Lehmann's chapters on General Bacteriology are a most admirable epitome of current knowledge on the subject and well repay the reader. The larger part of the second volume is devoted to special bacteriology and is so arranged as to facilitate the recognition of the most important species which may be encountered. This is done by means of synoptic tables, designed on a more or less dichotomic basis, at the head of each great division of the family, from these the student is referred to the detailed specific descriptions. A due sense of proportion is observed in the amount of space allotted to each species, those of practical importance being the more fully treated. A large amount of careful work appears to have been performed in the authors' laboratories at Würzburg in the way of correlating species which have been described under different names the task of identification is thus considerably reduced and we have found the work a more trustworthy guide to the recognition of unfamiliar species than any with which we are acquainted. The translation is accurate and readable, though here and there it is unmistakably American. We can recommend the book as a most useful adjunct to every bacteriological laboratory.

Handbook of Obstetric Nursing. By F. W. N. HAULTAIN, M.D., F.R.C.P. Edin., and J. HAIG FERGUSON, M.D., F.R.C.P. Edin. Fourth edition, revised and enlarged. Edinburgh and London: Young J. Pentland. 1902. Pp. 267, with Frontispiece and 37 Engravings. Price 5*s.*—This excellent little handbook for the use of obstetric nurses has now reached a fourth edition. The authors have revised the account of the management of labour and more especially that of the third stage. They have also drawn up rules applicable to the antiseptic management of labour, both in hospital and in private practice. The book has been carefully revised and brought up to date. It is a good example of the kind of book suitable for obstetric nurses and does not err on the side of giving too detailed information. The authors have again included in an appendix the very useful memorandum issued by the British Medical Association of the regulations proposed for adoption by the Obstetric Nurses Board.

The Life of St. Luke. By EDWARD CLAPTON, M.D., F.R.C.P. Lond., late Physician to St. Thomas's Hospital. London: J. and A. Churchill. 1902. Pp. 80. Price 1*s.* 6*d.* —This unpretending little work concerning the life of the patron saint of the medical profession consists in a catena of statements put together from the Gospel according to St. Luke, from the Acts of the Apostles, from Josephus, and from patristic writers. Besides these historical statements Dr. Clapton puts forward some theories of his own which are certainly reasonable enough in most cases. His theory that "the thorn in the flesh, the messenger of Satan," referred to by St. Paul, was "the mosquito produced malaria," Satan—i.e., Beelzebub—being the lord of flies, is ingenious and quite as likely to be true as any other theory. Dr. Clapton objects to physicians at the present day being called disciples of Æsculapius because, he says, the Asclepiades of Pergamos were quacks. Very likely they were, but so far as we know Æsculapius was not and the treatment as carried out at his chief shrine, Epidauros, was quite sound. We do not object to Christians being called disciples of Christ because the "Christian Scientists" are quacks.

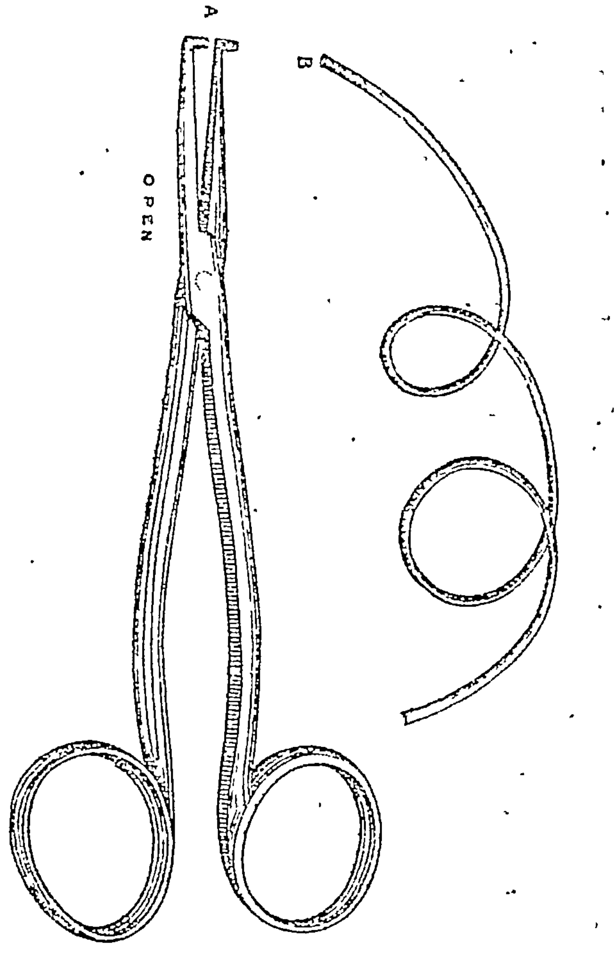
The Book of Asparagus, with Sections also on Celery, Salsify, Scorzonera, and Seakale. By CHARLES ILOTT, F.R.H.S., Lecturer on Horticulture to the Cornwall County Council, together with Chapters on the History, Decorative Uses, and Cookery of these Vegetables by the Editor. London and New York: John Lane. 1901. Pp. 108. Price 2*s.* 6*d.*—This is the first of a series of handbooks on practical gardening and is edited by Mr. Harry Roberts, F.R.C.S., who may be congratulated on having produced a useful and pretty little book on a very interesting subject. Asparagus is a well appreciated vegetable which has well-marked and well-known physiological effects on man; seakale, like most of the other members of the order to which it belongs, has antiscorbutic properties; salsify and scorzonera are nourishing and palatable vegetables and deserve to be more generally grown. Celery is, of course, a universal favourite, but celeriac is appreciated chiefly by those who associate it with bright and happy days spent in Italy. It hardly falls within our scope to discuss the culture of vegetables and it must suffice to say that Mr. Ilott generally gives good advice. His teaching on asparagus represents a position about midway between the most enlightened teaching of the best French specialists on the subject and the crass ignorance of the ordinary English gentleman's gardener. The most interesting part of the book is that contributed by Mr. Roberts on the history of the vegetables, and perhaps the most useful that on the methods which may be employed in preparing them for the table. The vegetable *entrée* is too much neglected in England, a fact to be regretted both from a gastronomic and from a hygienic point of view. The book is well printed and contains 17 illustrations, some of which are very old friends.

A System of Physiologic Therapeutics. Vol. IV. Climatology. Book II.—In the description and review of this volume which appeared in THE LANCET of April 26th, 1902, page 1189, it was omitted to state that the work is by F. Parkes Weber, M.A., M.D., F.R.C.P. Lond., with the collaboration for America of Guy Hinsdale, A.M., M.D. Dr. Parkes Weber states that the connexion in that review of Dr. Coan's name with the remarks on sea-bathing is erroneous. Fuller particulars as to the title, authors, and editor of the work will be found in THE LANCET of April 19th, 1902, page 1115, above the review of Volume III. Book I.

New Inventions.

NEW FORCEPS FOR THE INTRODUCTION OF DRAINAGE-TUBES.

DIFFICULTY having from time to time arisen in fixing Southey's fine drainage-tubing on the cannulas I have had made for me a pair of forceps which will undoubtedly do away with that difficulty. The illustration speaks for itself. Mr. Staniforth of Church-street, Cardiff, is the maker.



Cardiff.

T. GARRETT HORDER.

A NEW FORM OF SPLINTING.

As a general practitioner I have often felt the need that exists for some form of light cheap splinting which can easily be cut when wanted into any desired shape and size, for it is practically impossible for a country or suburban general practitioner to keep ready-made splints in sufficient variety of shapes and sizes for all the various fractures which he may at any time be called upon to treat. Gooch splinting is good and convenient but many splints, such as right-angled ones, cannot be made from it Poroplastic also is good but is rather heavy, expensive, and requires moulding Some time ago I made some splinting from corrugated boards—i.e., corrugated paper fastened between two sheets of cardboard By fastening two such corrugated boards together with the corrugations in one at right angles to the corrugations in the other I obtained a splinting which I have used for about a year This splinting has the following advantages —(1) it is light, (2) it is easily and quickly cut with a penknife into any desired shape, (3) it is quite strong enough for any ordinary splint except a long hip splint, (4) it requires very little or no padding, as the material itself is comfortable against a limb; (5) it is transparent to x rays, a rather important matter nowadays, and, lastly, (6) it is cheap. Further, it may be strengthened as much as can possibly be desired by the insertion of, wires, such as bicycle spokes, into some of the corrugations, and in right-angled splints some of the spokes will go one way in one set of corrugations and some at right angles in the other set of corrugations, and in splints longer than bicycle spokes, the spokes can be inserted from each end, overlapping in the middle of the splint. Also, by cutting the splinting into the desired shape, then inserting a sufficient number of spokes or other wires, it can be then bent into many shapes suitable for orthopædic purposes. For instance, I have used it successfully for splints for talipes plantaris to be worn at night instead of a Scarpa's shoe, the foot piece being forcibly bent round at right angles to the leg piece, and the angle can be easily strengthened by another such piece glued on to the outside Tapes or elastics are easily fastened between the wires or spokes to hold down the toes in cases of hammer toe, &c The bicycle spokes, which are very strong and tough, are easily cut into desired lengths by a special though cheap cutter or simply "nicked" with a file and then broken off. For x ray purposes these spokes can be withdrawn from all ordinary splints if desired without taking the splint off the limb and so again inserted. This splinting will not be so much required for stationary civil hospitals or by surgeons living near skilled instrument-makers, but by army and other moving hospitals, ambulances, and by the great numbers of general practitioners living in the country or suburbs who have to make their own splints as required

Messrs Arnold and Sons have recently made some of this splinting covered with white paper cardboard, in sizes of 30 inches square, and they can also supply the bicycle spokes and spoke-cutters GEORGE B BATTEN, M D Edin

Dulwich.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

An ordinary meeting of the Comitia was held on April 24th, Sir WILLIAM SELBY CHURCH, Bart, the President, being in the chair

The PRESIDENT announced that Sir Richard Douglas Powell, Bart., K C.V O, had consented to act as the delegate of the College at the Medical Congress to be held in Cairo in December and that Dr J F Payne would represent the College at the tercentenary celebration of the Bodleian Library at Oxford The President also announced that owing to the illness of Dr J W Washbourn the Croonian Lectures would not be delivered until November The President further informed the College that the following Fellows had been appointed to act as a committee to make suitable arrangements for the erection of stands and decorations at the time of the Coronation The College Officers, Dr C. Theodore Williams, Dr W H. Allchin, and Dr Oswald A. Browne

The following gentlemen having passed the required examination were admitted Members of the College Dr Joseph Shaw Bolton, Dr William Philip Sutcliffe Branson, Mr Gerald Godfray Giffard, Dr Charles Herbert Melland, Dr Sidney Vere Pearson, Dr Edward Furniss Potter, and Dr Walter Henry Maxwell Telling

Licences to practise physic were granted to 123 gentlemen who had passed the required examination. The Examiners for the Murchison Scholarship reported that they had decided to advise the College not to award the scholarship for this year

The following Members of the College were on the nomination of the council elected to the Fellowship Dr Henry Carr Maudsley (Melbourne, Australia), Dr William Camac Wilkinson (Sydney New South Wales), Dr Frank Montague Pope, Dr Edward Malins, Dr William Alfred Wills, Dr Thomas Hancock Arnold Chaplin, Dr William Page May, Dr Arthur George Phear, Dr George Francis Blacker, Dr John Fawcett, Dr Herbert Campbell Thomson, Dr Albert Sidney Frankau Grünbaum, Dr James Barr, and Dr Joseph John Perkins

The following communications were received 1. From the secretary of the College of Surgeons reporting certain proceedings of the Council on April 10th 2. From the General Medical Council submitting certain questions with respect to the courses of study in chemistry, physics, and biology required from candidates for the conjoint diplomas, and announcing that the examinations of the Colleges in those subjects will be visited and reported on for the Council during the present year

A report was received from Dr NORMAN MOORE on the proceedings of the General Medical Council at the special session held in February last

Dr FREDERICK J SMITH submitted the draft of a petition from an Association of Licentiates of the College and of Members of the College of Surgeons of England, and asked permission that the petition might be presented to the College by a deputation at a future date. After some discussion in which Dr MOORE, Dr ALLCHIN, and Dr PAYNE took part, it was resolved, on a motion proposed by Dr SMITH and seconded by Dr DAWSON WILLIAMS, that leave should be given for the presentation of the petition, but that it was not the wish of the College that this should be accomplished by means of a deputation.

A report was received from the Committee of Management dated March 10th. The Walsall Municipal Science and Art Institute was recognised for instruction in chemistry, physics, and practical chemistry The regulation recently adopted by the General Medical Council with respect to the attendance at a fever hospital in the case of a registered practitioner who desires to obtain the diploma in public health was also referred to and it was resolved that the Committee of Management should draft a letter to the General Medical Council drawing the attention of that council to the disadvantages under which the candidates from London medical schools are placed by the impossibility of their obtaining the necessary instruction at the hospitals of the Metropolitan Asylums Board.

A second report was received from the Committee of Management dated March 17th, in which it was recommended that the course of clinical instruction in lunacy given by Dr T Claye Shaw at St. Luke's Hospital, Old street, London, should be recognised as fulfilling the conditions of Clause 10, Section 1, of the regulations of the Examining Board in England

Both these reports were adopted After some further formal business the PRESIDENT dissolved the Comitia.

FESTIVAL DINNER OF ST MARK'S HOSPITAL.—Sir Joseph Dimsdale, M P, the Lord Mayor of London, presided over the festival dinner of St. Mark's Hospital, held at the Hôtel Metropole on April 24th to celebrate the sixty sixth anniversary of the hospital. After the usual loyal toasts had been duly honoured the Lord Mayor gave the toast of the evening, "St Mark's Hospital.' He pointed out that in collecting funds for the hospital they were under a certain amount of disadvantage because the institution rendered assistance to persons suffering from diseases that prevented the friends of the charity from pleading for help with the same freedom and openness in public that was possible in the case of other hospitals There was an assured annual income of a little over £2000 a year and that had to be increased to £4500 In the course of the evening it was announced that the list of donations reached a total of over £2000 The following gentlemen spoke in the course of the evening Mr R B. Martin, M P (treasurer), Mr Alderman and Sheriff Bell, Mr D H Goodsall, Mr F S Edwards, Mr E F Carey, and Viscount Dungarvan.

THE LANCET.

LONDON: SATURDAY, MAY 3, 1902.

Some Points Relating to Massage.

THE Society of Trained Masseuses have recently had an opportunity of hearing an address from Sir WILLIAM H. BENNETT which contained many points of direct interest to the medical profession. It is an old saying that there is probably no instrument that is powerful for good which is not also powerful for evil and the history of massage amply confirms this view. Sir WILLIAM BENNETT gave an instructive account of his recollections of the old-fashioned "rubbers"—"very respectable people, rather portly in figure as a rule, strictly honest according to their lights; their main purpose seemed to be the rubbing away of knots in muscles which did not exist and the dispersing of curious conditions of the veins which were also of doubtful existence." From this it will be seen that the earliest form of massage was more or less of the fraudulent description which the Society of Trained Masseuses has been incorporated to resist. Unfortunately, amongst the laity there is apt to spring up a fashion for some particular form of medical or surgical treatment from which quacks reap a rich harvest. Such a tendency can only have one certain result and that is to bring into disrepute what may really be a most valuable therapeutic measure. Then, rather than appear to pander to a popular error, some practitioners refuse to make any use of the remedy: massage and hypnotism have both suffered in this way. In suitable cases and administered by proper and trained hands massage is admittedly of great value in the treatment of certain arthritic and muscular affections and in particular in diseases of the nervous system, both organic and functional, while it has proved its efficiency in some conditions in which there is failure of nutrition. Yet owing to the manner in which massage has been misapplied there has been a natural tendency amongst many members of the medical profession to use it as little as possible. Quacks have prescribed it, and their prescriptions (as well, for that matter, as those of the medical profession) in respect to massage have been exhibited too often by young women devoid of the slightest knowledge of their subject. Moreover, the way in which the word "massage" has been employed as a cloak for immoral practices has made it stink in all men's nostrils. This, of course, should not be allowed to affect legitimate treatment by the methods of massage, but apart from the attempt of the *fille de joie* to pose as a *sœur de charité*, some of the distrust of massage has been due to the ignorance or incompetency of many of the professional manipulators and to the absurd and extravagant efforts to proclaim it as an exclusive method of treatment.

Within recent years, however, many of the difficulties which at one time beset manipulative treatment have been gradually overcome. Classes have been formed under the guidance of skilled teachers in which male and female attendants have been carefully trained in a thoroughly scientific manner and have acquired a good knowledge of the theory and practice of massage. But something more than this is necessary. It is not difficult for any person to acquire the requisite knowledge of the technique, but certain personal characteristics in the masseur or masseuse are absolutely necessary. Sir WILLIAM BENNETT, in speaking to the Society of Trained Masseuses, referred at length to the absolute necessity that the person who undertakes to administer massage must be physically fit for the task. He rightly suggested that physicians who have had extended experience in the use of massage must have found many times that the masseuse has had a depressing effect upon the patient owing to her own personal peculiarities; and he no less rightly explained the existence of such attendants by pointing out that there are a large number of philanthropic people in the world who are always anxious to assist, either by advice or pecuniary help, others who are in less fortunate circumstances than themselves. Ill-directed kindness has led to the position. Many women who have failed in other callings, generally from ill-health or want of strength or even from some physical deformity, have been sent by philanthropic friends to receive a course of instruction in massage with a view to the gaining of a livelihood. The launching of such persons into the calling of massage is, we maintain, unfair to the individuals themselves, because they cannot possibly succeed; it is unfair to the general body of those who practise massage; and it is especially unfair to any patients who may happen to fall into the hands of persons quite unsuitable to carry out the treatment prescribed. If there is one quality more essential than another in those who practise massage it is that they should be able to exercise a wholesome, invigorating influence upon the patients; but if the masseur or masseuse be the victim of an obvious physical defect or be in bad health an exactly opposite effect can hardly be avoided. A similar result will also follow if the masseuse be wanting in the ordinary amount of tact and kindly feeling towards the patients whom she is asked to attend.

The formation of the Society of Trained Masseuses was really called for if manipulative methods were to be rescued from the keepers of bagnios, from quacks claiming to heal all diseases, and from the hardly less dangerous hands of the uninstructed young lady. One of the essential points for the effective application of massage is that it should only be carried out under the orders of a medical practitioner, for attempts by massage-attendants to treat patients on their own initiative can end only in failure. The fact that a masseuse is a member of the Society of Trained Masseuses is not only a guarantee that she has been well trained but ensures that she will not attempt to practise on her own account. There is a great danger, moreover, that a larger number of persons, especially women, will learn massage than can find employment, and as a matter of fact we believe that already the supply exceeds the demand. By only admitting as members of the society women who are in every way suitable for the calling great assistance will be rendered to the practitioners who make use of massage in the course of their practice and a deterrent to the overcrowding of the calling will thus be established. While wishing the Incorporated Society of Trained Masseuses continued success we would suggest that male attendants should likewise form a kindred association, or that the existing society should so alter its constitution as to admit *both men and women to its body. We strongly urge that* the practice of masseurs should be confined to men and that of masseuses to women. This is desirable from many points of view, most of which are too obvious to make it necessary to enter upon the matter here. The masseur is therefore as necessary to the medical practitioner as is the masseuse, and the same steps should be taken to regulate their supply and standardise their attainments.

The Sanitary Oath.

SIR FRANCIS JEUNE and Mr. Justice GORELL BARNES have had posted outside the two courts of the Probate, Divorce, and Admiralty Division notices to witnesses calling their attention to the fact that they may be sworn in the Scotch manner before giving evidence. That is to say, they may be sworn with uplifted hand repeating a solemn invocation to the Deity, instead of taking a book and kissing it after listening to a form repeated by a minor official of the court. The notice to which we refer is repeated outside one of the courts of the Chancery Division and we have every hope that it may become universal. As it is, we may claim the publication of such a notice in the High Court of Justice at all as a victory for a cause that we have long advocated. We have for many years contended that the oath by kissing a book has nothing to commend it, while it is nasty and may become a means of propagation of disease; and we have seen with regret that the statutory permission to swear in the Scotch fashion was, as a rule, not known by witnesses and frequently, also, that judges, coroners, and magistrates were ignorant of it. This permission was given by the Fifth Section of the Oaths Act of 1888, a statute which we owe to the late Mr. BRADLAUGH. The Fifth Section provides that "if any person to whom an oath is administered desires to swear with uplifted hand in the form and manner in which an oath is usually administered in Scotland, he shall be permitted to do so and the oath shall be administered to him in such form and manner without further question." The primary object of this section was, we believe, to allow Scotch witnesses to be sworn in English courts in the manner to which they were accustomed. It is, however, obviously so worded that any one who does not wish to kiss the book may avoid doing so without his religious or other motives becoming the subject of any inquiry. No doubt it would be more satisfactory if a form of oath excluding the kissing of a book were directly prescribed by the legislature, but the power to dispense with the practice, long denounced by us as dirty and dangerous, is a step in the right direction. We trust that the power so given will soon be universally known. It has, however, been to a large extent ignored by coroners, while one county-court judge only, so far as we know—his Honour Judge EMDEN—has been active in calling attention to the Act, posting notices relating to it in his court and doing his best to introduce the sanitary oath among witnesses giving evidence before him. Presumably the small-pox epidemic and the spread of knowledge of sanitary laws have contributed to break down the well-known conservatism of the law courts and to discourage a procedure that had somehow become universal.

The form of swearing by kissing a book is purely one of custom. There is no direct authority for it in any Act of Parliament, or rule, or book of practice. The date also of its introduction is unknown, but this is not because it has been lost in the mists of antiquity, for it is fairly certain that, so recently as at the end of the seventeenth century, if the form existed it was not in any general use. It has been pointed out that COKE in his Institutes makes no mention of kissing the book but writes of the "corporal oath" as thus named because the witness touched with his hand a portion of the Scriptures, and this aspect of the oath no doubt survives in the familiar warning of the usher to the witness to remove the glove before taking the testament for the purpose of kissing it. It is also observed that in the "Book of Oaths," of which an edition was published in 1689, there is no mention of kissing a book. How the kissing originated is, we believe, almost as much a matter of speculation as is the date at which it became frequent or universal. The laying of the hand on the Gospels in swearing is, no doubt, of great antiquity, while the laying of the hand on the altar of a deity in invoking the deity to witness a statement or promise is older than the Gospels. The laying of the hand on the Gospels has its parallel in other countries besides England. The kissing of the book is, however, we believe, peculiar to England, or to England and Ireland, and it is not quite easy to assign its origin to the kissing of relics when we apparently find it introduced in England after all veneration for relics had been swept away and made illegal. It is worth noting that English people were more addicted to kissing once than they are now. Kissing as a form of salutation was so common among them that it excited the interest and amusement of foreigners. ERASMUS refers to it and a Hungarian gentleman who visited London and moved in good society in 1663 was much struck with the way in which men kissed ladies when they greeted them, where Hungarians would have shaken hands. Even Frenchmen in the middle ages held kissing as a peculiarity of the English nation, much as we remark upon it now among the French. It is, therefore, at least possible that the kiss bestowed upon the book in taking an oath may have been not so much a kiss of veneration as a form of salutation or acknowledgment by bodily contact, somewhat more ceremonious than manual contact, but still not associated with any great feeling of solemnity.

That there is any solemnity now surviving in the oath as usually administered in a court of law none will maintain. The rapid gabble of the usher or officer of the court saves time, and this may commend the unceremonious ceremony to the tribunal. The witness not infrequently kisses his thumb and believes that all danger of incurring the wrath of the Divinity if he forswears himself is thus avoided. We can well understand that the perjurer would prefer the oath so taken to the Scotch form. He would not lightly bear false witness who had raised his hand to heaven and had repeated the words solemnly dictated to him: "I swear by Almighty GOD, and as I shall answer to GOD at the great Day of Judgment, that I will tell the truth, the whole truth, and nothing but the truth, in so far as I know or as the same shall be asked of me." It is, however, urged that if the Scotch oath now permitted became universal through being made compulsory delay would result, particularly with uneducated and stupid witnesses. In order to obviate such delay Mr. F. A. STRINGER, in a letter published in the *Times* on Jan. 12th, 1897, suggested that the Scotch form of oath might be administered according to a method suggested by the practice of French, Belgian, and Spanish courts. In this case the person administering the oath would repeat a form commencing with the words, "You do swear by Almighty GOD," and when he had concluded the person sworn would hold up his hand and say, "I swear by Almighty GOD." We need hardly point out that an oath by Almighty GOD should be binding upon members of all creeds which involve belief in a supreme deity, and that an oath so generally applicable must be to some extent a convenience. In any case, it must not be forgotten that whether the oath is more or less binding to the conscience when administered without bodily contact of a book, there are still the legal penalties of perjury to deter those whose conscience is easily appeased.

Many years may possibly elapse before fresh legislation renders universal and obligatory a sanitary and at the same time an impressive and a reverent form of oath. The step forward upon which we now congratulate those who have urged reform consists in the endeavour of certain judges of the High Court of Justice to make better known the Scotch form which is permitted, but not ordered, for all witnesses, whether Scotch or not. We note, moreover, that these judges preside in that Division in which in 1886 the late Mr. Justice BUTT ridiculed the objection of Dr. T. HARKNESS of Derby to kiss a book which just before had been kissed by two common prostitutes. At least one other medical man had before this called attention to the question, and we had lent support to his view. Since then medical men have frequently protested against being obliged to kiss a book, and since 1888 many have availed themselves of the Act of that year when aware of it and when not prevented from doing so. And we have commended their action. We have not, nor has anyone, proved or asserted the frequent spreading of infectious disease through the taking of the witnesses' oath. We have, however, insisted that kissing the book was uncleanly and that it might in conceivable cases be dangerous. In one case in 1898 Mr. F. D. LYS, late medical officer of health to the District Council of Wareham and Purbeck, ascribed, in his annual report to the council, the death of a policeman to acute ulceration of the throat contracted through taking the witness's oath at petty sessions at Wareham. Besides ourselves many individual medical men and laymen since 1885 have contended on behalf of a sanitary form of swearing, conspicuous among them being Mr. F. A. STRINGER, the author of "Oaths and Affirmations," an experienced official of the High Court of Justice, and Mr. F. W. LOWNDES, late senior surgeon to the Liverpool Police, who has taken a constant and energetic part in the struggle from its commencement. That the success obtained should have come slowly and should be incomplete even now affords a fair instance of the difficulty with which reforms are sometimes brought about, even though they are admitted on all sides to be desirable. It illustrates also the indifference of the general public to sanitary questions that are not brought vividly before them by the actual presence of disease.

◆

The Affairs of the Royal Orthopædic Hospital.

THE affairs of a hospital—its administration, management, and pecuniary arrangements—must always be to medical men as well as to the general public of scarcely less interest than the purely professional side of these charitable institutions. And when difficulties and disagreements arise among those controlling the administration of hospitals it is as a rule a wholesome thing to illuminate the corners of the committee-room wherein the discussions have taken place, so that no one may have the unfortunate impression that things are being done in the name of popular charity that are not for the popular good. Publicity in such matters generally makes for what is just and right, and by freely ventilating disagreements we most easily get the big battalions of the public behind those with whom victory ought to rest. It is with this object that we return to discussion of the affairs of the Royal Orthopædic Hospital. We make no further excuse for once again urging the need for full investigation into the proposed sale of the site of the hospital in Hanover-square. The suggestion that by calling attention to the existence of dissension we may actually damage the institution has been made, but it is a ridiculous one. Every sensible supporter of a hospital likes to feel that his subscription is given where it is rightly spent, and the suspicion that a charity is being mismanaged is vastly more prejudicial to its future than any demand for enlightenment can ever be.

Curiosity has been naturally excited by the fact that the authorities of a hospital possessing a freehold site the value of which is still rising should be anxious to sell their magnificent position and to build a home for themselves elsewhere, while burdening themselves with a rent. The policy is so extraordinary, having in view the grave financial difficulties of other London hospitals, that those responsible for it ought to wish to make it intelligible. Either the need for ready money must be urgent to an extent that is unknown to the public or the demand for an orthopædic hospital upon another site must be more pressing than we, or any members of the medical profession, have ever suspected. The committee of management, however, which is proposing the sale, has made no attempt to demonstrate the need for either. Indeed, if ready money were the object the committee possesses in its freehold a means of raising it, while the fact that a sum of £2000 was spent recently upon the repairing of the present building points neither to acute need of cash nor to a long-established belief that Oxford-street is an unsuitable locality for the work. On one thing information is particularly needed. If a new building is really desirable why is not the very reasonable suggestion of the opponents of the sale considered? They desire to rebuild the hospital upon its present site, believing it an unsound financial proceeding to sacrifice the freehold. Their view is that the hospital should be rebuilt on part of the site and that the income of the charity could be increased by letting the remainder at a high rent. With a frontage upon Oxford-street and another upon Hanover square the prospects of letting any part of the premises that could be spared as shops or offices must be exceptionally good, a fact that is certainly well known to those who are now proposing to pay an enhanced but, as we believe, inadequate price for the premises. The committee, however, seems bent upon a sale and an alternative scheme of any kind receives no serious consideration from its members We should like to know the reason. We are perfectly willing to believe that the motives of the committee are based purely on a desire to improve the welfare of the Royal Orthopædic Hospital and we deplore the insinuations that have been made to the contrary as stupid and unjustifiable. But granted the excellence of the motives yet to an impartial eye the improvement that should accrue upon such action is obscure; and, together with the minority who oppose the sale, we ask the simple question Why is it necessary to sell the site? There can be nothing intrinsically wrong in the site for it is one which keeps the institution in the public eye. If it is the building which is radically vicious, why in the first place spend a large sum of money repairing it? And in the second place, why not re build on the old site? Lastly, if satisfactory reasons are forthcoming why the site must be sold every effort should be made in the interests of the charity to get the largest possible price. At least if it must be sold let the site be put up for public auction and the market be fairly gauged

We have before us as we write a valuation of the site made within the last month by a firm of estate agents competent to give an opinion upon the matter After saying, *inter alia*, that "properties in these highly favoured positions, being seldom in the market, are increasing in value to an incredible extent," the estate agents categorically declare that £40,600 is the wrong price for the freehold, and that a 99 years' lease of the ground at £1400 a year, with an option to purchase for £40,600 in three years' time should not be granted These, we learn, are the proposed terms of sale. The agents give their reason for believing that the site should realise at the present moment at least £7000 more, while they state that far better terms could be obtained in three or four years' time. We find their views convincing in the absence of any explanation why immediate sale of the site is compulsory And if the mere facts of the situation at the Royal Orthopædic Hospital call for explanation a closer examination into the history of the proposed sale leaves the inquirer still more in doubt as to the standpoint of the committee. The sale of the site of the hospital was first proposed by a committee in 1899 and that committee lost its position of authority on this very point It was ousted largely, we believe, through the efforts of the present chairman who was elected, it was understood, in maintenance of a no sale policy Yet before long the new chairman and his supporters are found furthering the designs of their ejected predecessors and even outdoing them in their eagerness to sell the site of the hospital There is no reason whatever why a man or a committee should not change in mind, but when the financial affairs of a public charity are concerned, the reasons for recanting should be forthcoming willingly

Annotations.

"Ne quid nimis."

THE ENDOWMENT OF HIGHER EDUCATION

THE appeal of University College, London, for a million pounds sterling has drawn attention to the very urgent need which exists for the endowment of higher education in Great Britain. Under certain circumstances elementary teaching may be self supporting, the payments of the scholars providing sufficient to defray the cost of the school premises, the books and materials needed, and the remuneration of the teachers. Yet it is being recognised that a very large part of even the elementary education of the country must be assisted by the State, or to a great extent supported by voluntary contributions If this is so where elementary education is in question, where the necessary acquirements of the teachers and the equipment for teaching are not of a high standard, much more must it be the case where higher education is in question. It has been long known that the fees which students are able and willing to pay for instruction are totally inadequate to reimburse the teaching institutions for the expenses incurred It has been estimated that the average cost in French and German universities of educating a student amounts to between £50 and £70 a year and the expense in this country would surely not be less. Yet the annual educational fees required from a student in most British universities and institutions of university rank do not exceed £20 or £30 It is clear that the difference between these amounts must be supplied by endowment. Moreover, the recent developments in science have greatly increased the expense of the equipment necessary for efficient teaching, and the development of many sciences makes it no longer desirable or even possible for one lecturer to deal with all the branches of one science The scientific method, too, has invaded departments of study which at one time were dealt with empirically, and thus new forms of applied science have come into being Each of these branches of learning must be taught by professors and lecturers who have devoted special attention to the subject. For these adequate remuneration must be provided or it will be impossible to obtain the best men £300 a year is surely little enough to attach to any lectureship and £800 would be a more desirable stipend Further, in most subjects in addition to the lecturer there should be assistant lecturers and demonstrators are also equally essential. A most important branch of all scientific institutions is research work, for to neglect to aid in the advance of a science is to drop behind. No institution of university rank fulfils its destiny if it fails to provide facilities for research work for the lecturer himself, for his assistants, and for the senior students A great item is the cost of fitting up modern laboratories, and more expensive still is their maintenance In this country the need for the endowment of higher education was formerly fully appreciated and the Universities of Oxford and Cambridge are noble monuments of bygone munificence. Even in recent years there have not been wanting instances of the endowment of higher education—among them may be specially mentioned Mason's College, Birmingham—but other countries have done far more In our own times the University of California has been endowed with £9,000 000 sterling, the University of Chicago has received £2,500,000 and the Johns Hopkins

University £1,400,000. On the continent of Europe we find the State recognising the value and the needs of a University education and contributing with no niggardly hand to the expenses of the universities. In Germany there are 22 universities and these receive more than £700,000 a year from the State, and in France a like sum is granted to its 16 universities. In this country it is almost hopeless to expect substantial help from the Government for the endowment or support of higher education, and we must therefore look to private individuals for the funds to establish and to maintain institutions of university rank. We can imagine no more beneficent object for the liberality of the wealthy. Efficient higher education is one of the most essential elements of our national life. University College, London, has done good work in the past, and especially worthy of mention and of interest to all medical men is its medical faculty with its long list of distinguished alumni. Its funds are, however, entirely insufficient for the due prosecution of its work, and its probable incorporation in the University of London makes it more necessary than ever that its endowment should be greatly increased. A million pounds sterling is a large sum of money, but unfortunately the present low rate of interest necessitates the allocation of a far larger amount of capital than would at one time have been required to produce the income urgently needed. Adequately endowed, University College, London, should prove of the greatest value in making the new University of London a real university in the best sense of that word.

WEEK-ENDS.

To point to the hurry and stress of modern town life as the cause of half the ills to which flesh to-day is heir has become almost a commonplace in etiological diagnosis. The old-fashioned, so to speak time-honoured, complaints might almost excite a medical man's pity, so much do they seem to be crowded out by those active widespread young fellows, neuritis, neurasthenia, and a whole young family of nervous illnesses, the offspring of the strained existence of to-day. A chain is as strong as its weakest link and to-day it appears that the nervous system is the weak link of the organism. The weakness is not natural. It is acquired because the strain upon this link is so often almost constant and out of proportion to the wearing power, so to speak, of the material. Whether as generations advance individual nervous systems will more easily bear the labours asked from them or not, at any rate it may fairly be assumed that in the early days of any new style of life the generations born under an old *régime* have, to speak colloquially, the worst of it. Their children cope more easily with the new necessities. They are earlier confronted with them and new arrangements which perplexed and worried their parents become habits easily borne and therefore not to be reckoned among the trying elements of existence. Thus we may imagine future generations perfectly calm among a hundred telephones and sleeping sweetly though air-ships whizz among countless electric wires over their heads and a perpetual night traffic of motor-cars hurtles past their bed-room windows. As yet, it must be sorrowfully confessed, our nervous systems are not so callous. Some of us still start at the telephone-ring and find the irregularities of the instrument a source of irritation and worry. Many of us are actually nervous at the sudden appearance of a motor-car round the wrong side of a London street-corner. The result of countless repetitions of these trials, small though they may be singly, is not to be lightly estimated. It is not only in the case of infectious diseases that a virgin soil affords the most favourable condition for a fertile growth and spread of the morbid influence. Our readers are familiar with the ravages perpetrated by such diseases as syphilis and small-pox when they fall for the first time upon a savage population. It is not straining an analogy too much to compare with these the effect upon civilised populations of large cities of the manifold stresses, hurries, worries, and anxieties of modern existence in its latest form. The savage communities always knew disease but syphilis and small-pox were new forms. Town populations always knew worry and excitement—electric communication and rapid locomotion provide their new forms. Fortunately, the very causes of nerve exhaustion, so far a improved rapidity of locomotion may be counted one o them, provide one important counteracting feature of town life at the present day. We are alluding to the facility with which those whose week-days are spent in city toil may spend the seventh in breathing the fresh air and beholding the innocent joys of the rustic. To the hard-working Londoner the value of the week-end properly used is hard to over-estimate. From the eager broker and worried business man to the stifled seamstress and toiling artisan there are few who cannot find further or nearer from the metropolis some fresh and open spot where they may replace the evil atmosphere of the office or the factory. Without trains, electric tramways, and motor-cars such a wholesome change of scenery and surroundings would be scarcely possible in the limited time available. We do not wish to underrate for a moment the value of parks and open spaces—the "city's lungs" as such places have been aptly called. For many these afford the only possibility of a Sunday in at any rate comparatively fresh air. Those large numbers, though, who habitually find the Sabbath's rest in a day's wholesome exercise at some little distance from their work-a-day centre may spare a moment from the usual condemnatory attitude towards the bustle, rush, and clatter of up-to-date locomotion to bless the means which enable them so profitably to enjoy that day which a far-seeing design has allotted to the recuperation of striving Christianity.

OLD BELIEFS CONCERNING TOBACCO.

THE belief that tobacco-smoke is a disinfectant has long been popularly held and THE LANCET has been lately invited by the *Daily Chronicle* to "spare a moment from the pursuit of germs" to speak upon the point. In doing so we are not departing from that which our excellent contemporary holds to be our permanent engagement, for the question has much to do with germs, though the classic experiments with tobacco-smoke and cultures of bacteria prove little. As long ago as 1888 Dr. Paul Tassinari of Pisa subjected the germs of various deadly diseases (such as anthrax, cholera, and typhus fever) to the action of dense clouds of imprisoned tobacco-smoke during periods of 100 to 150 hour and he came to the conclusion that in most cases, and especially when large cigars had been employed as generators, the development of pathogenic bacteria was either partially or wholly arrested. But nobody retains smoke in his mouth for 100 hours at a time! An occasional pipe, indeed, scarcely counts in comparison with Dr. Tassinari's intense soaking process. Besides, under the conditions imposed by the Italian investigator would not the smoke of coal or wood produce the same results as that of cigars? It is recorded, says the *Daily Chronicle*, that during the Great Plague children were told to smoke in their schoolrooms. The idea was probably borrowed from the custom of the buriers of the dead on their way, in charge of dead-carts, to Holywell Mount. We read in "A Brief Abstract of the Virtues of the American Tobacco Plant," published in 1783, that at first these persons only used tobacco as a deodoriser, "little thinking that what they used for momentary relief would prove a constant preventative. When the Plague was happily stayed, the Virtues of Tobacco began to be investigated, it was found that those persons who plentifully used it, either in smoking or snuffing, had most wonderfully escaped the dire contagion; for though they visited the chambers of the sick, attended the funerals of cartloads at a time, they unexpectedly avoided the infection." The writer even goes so far as to advance the theory that since Europe took to smoking epidemics had greatly decreased and we find him stating the belief that dealers in tobacco were secure from plague infection. Yet he can assign no reason why tobacco should prove so valuable as a disinfectant except in so far as it fortifies the head against "exhalations." Workmen in tobacco factories are often cited as being immune from cholera and other epidemics. It is interesting to trace this belief back. Abroad it probably received its first impetus in Toulouse, where shortly before the Revolution the workmen in the State tobacco factory are said to have remained immune during a deadly epidemic of *suette* (sweating sickness). The belief, according to Parent-Duchâtelet and d'Arcet, who reported to the French Government upon the health of workers in tobacco in 1829, was probably much more ancient in that neighbourhood. It may perhaps be of the nature of folk lore. They cite the opinion of the medical man attached to the Bordeaux State factory who writes to them expressing his belief that this local industry was a veritable blessing to a damp and foggy town. "The piquant and ammoniacal emanations arising from the tobacco qualify the air and diminish its insalubrity." Before the establishment of this factory, he goes on to remark, the poorer parts of Bordeaux had been ravaged by epidemics and contagions now unknown. The death rate among the tobacco workmen is, he adds, very low, while very few cases of illness occur among them, although they are in general ill-lodged and clothed and even worse fed. Parent-Duchâtelet and d'Arcet seem to support the views of their correspondent, and we have no new facts to add in evidence of the value of tobacco-smoking in epidemic disease. As yet, at any rate, there is nothing authoritative to be said.

THE PURIFICATION OF RIVER WATER.

AT a meeting of the Association of Municipal and County Engineers recently held in Birmingham a paper on the Filtration of River Water was read by Mr. J. A. Jenkins, C.E. There are, he said, three methods of dealing with river water that is liable to pollution: (1) sedimentation in storage reservoirs; (2) slow filtration through sand; and (3) coagulation by the addition of chemicals with subsequent rapid filtration. The advantages of sedimentation could not, he thought, be too highly advocated. There was no doubt that a reduction in the numbers and vitality of harmful bacteria was effected by means of the bactericidal action of the harmless species working with the help of sunlight and air and considerable numbers were also got rid of during the process of precipitation. As the result of careful observation it had been found that if a high degree of bacterial efficiency was to be maintained the rate of filtration must not exceed four lineal inches per hour. This was practically two gallons per square foot per hour, or rather more than 1,000,000 gallons per acre in 24 hours. It was essential that the rate of filtration should be regular, as otherwise the bacteria caught on the upper layers of sand might be washed down into the lower coarser material or out of the filter altogether. Mr. Caink of Worcester said that sand filtration gave the best health statistics. Several towns supplied with water from the new red sandstone, which is supposed to be very pure chemically and bacteriologically, had a typhoid fever case-rate of from 150 to 200 per 100,000 of population, while others supplied with river water receiving sewage pollution, when effectively filtered in an adequate area, even without sedimentation, had typhoid fever case rates varying from 20 to 25 per 100,000 of population. With reference to the foregoing, the views entertained by the people of Egypt on the subject of potable water may be of interest. Nile water, they say, should never be filtered. Not only does the mud it contains add to its nourishing qualities but it also makes it wholesome. Even educated Egyptians, some of them members of the medical profession, sustain this theory and endeavour to justify it scientifically. According to their contention every human being admits innumerable microbes into his system every moment of his life. The majority are probably innocuous but unquestionably some are more or less deadly. Now it is well known that microbes are continually engaged in internecine war but nature has so adjusted the strength of the combatants that the net result for their human host is health. If, however, in a purblind attempt to improve on nature, that host should be foolish enough to meddle with her far-seeing arrangements he will inevitably disturb the equilibrium of the microscopic belligerents and end by doing himself an injury. Specious reasoning of this calibre is proudly advanced as unanswerable by the possessors of a little learning, but when they are asked to account for the fact that since the introduction of modern sanitation the duration of life has sensibly increased and, a still more telling argument, that the time lost by sickness has greatly diminished, it is the drinkers of shallow Pierian draughts who themselves remain dumbstricken.

THE TORBAY HOSPITAL.

DIFFICULTIES have of late arisen at the Torbay Hospital in reference to the tenure of office of the medical staff and the method of electing its members. The following are the main facts of the case as far as the matter has gone at present. At the annual meeting of the governors of the Torbay Hospital in February, 1901, the rule relating to the election of the honorary medical staff was, at the instance of the weekly board, altered so as to make the election annual, though some members of the staff protested at the time against the alteration. The staff are elected by a special board consisting of the weekly board (14 members) and the honorary medical staff (eight members). It was pointed out at the time that the staff would not care to vote for their own election. When the special board was summoned this year to elect the staff the latter, not caring to vote for themselves, did not attend the meeting. There were nine vacancies and the honorary secretary handed round ballot papers containing the name of each member of the staff, with ruled columns opposite, the one headed "For" and the other "Against." In the case of two of the staff more votes were given "against" than "for." The chairman accordingly ruled that these two were not elected. Advertisements were then inserted in the newspapers asking for candidates for the vacancies. In the meantime the two rejected members of the staff called a meeting of the local profession, which was attended by practically all its practising members, and a motion was unanimously carried pledging all the members not to apply for the vacancies until the annual rule had been rescinded. When the board met to elect there were no candidates. A special meeting of the governors was then held on March 21st to rescind the new rule and substitute for it practically the old rule. The chairman allowed no amendments to be put. Eventually a motion was carried adjourning the meeting for a month in order that a conference might be held between 14 members of the Torquay Medical Society and the weekly board with a view to settle their differences. The Torquay Medical Society is composed of nearly every registered practitioner in Torquay, together with many from the surrounding districts. The society met and chose as its representatives 14 of its members who practised in Torquay and who were in no way

Mauritius, a telegram from the Governor received at the Colonial Office on April 25th states that there were no cases of plague for the week ending April 24th. On the principle that "forewarned is forearmed" the medical officer of health of Bristol, Dr. D. S. Davies, has issued a circular to medical practitioners in his district pointing out that though at present there is no known case of plague existing in these islands, yet the possibility of its introduction, especially into seaport towns, is ever present. The circular draws attention to the need for regarding with suspicion any case of pneumonia among sailors recently arrived from suspected ports or among dockyard labourers engaged in unloading cargoes from such ports. Any case also presenting the smyptoms of fever with adenitis after possible exposure to infection should be viewed with suspicion. The circular concludes by stating that any communication from a medical practitioner to the medical officer of health with a view to securing a bacteriological diagnosis will receive attention.

HOLIDAYS FOR POOR CHILDREN.

THE Ragged School Union and Shaftesbury Society, which was founded nearly 60 years ago, sent last year some 6000 children from the unhealthy and crowded back streets of the metropolis to the country or the seaside for a fortnight or more. This year the society wishes to repeat this useful work and its appeal for funds will be, we trust, readily responded to by those who are able to help. One child can be sent away for a fortnight's holiday for the sum of 10*s.* and it is difficult to estimate the value, both physical and mental, of a fortnight's holiday in the pure air of the country to the children of the slums. Donations should be sent to the secretary, 32, John-street, Theobald's-road, London, W.C. By the way, the question of the risk to the country districts of spreading small-pox among them through the medium of the little holiday visitors, though small, must not be disregarded. We trust that the society will take every precaution in the matter.

THE OBSTETRICIAN—PHYSICIAN OR SURGEON?

IN our issue of April 5th, p. 979, we referred to the troubles which have arisen at the Lincoln County Hospital concerning the action of the physician in charge of gynæcological cases performing operations such as abdominal sections. The matter was referred to the weekly board and that body decided that the gynæcologist in question was within his right in performing such operations as we have mentioned. The members of the staff who are also members of the weekly board attended but did not vote. The matter was then referred to the quarterly board of governors which met on April 10th and by 16 votes to 14 it was resolved that the decision of the weekly board should stand. This is but a small majority to decide a question which has obviously given rise to a great deal of heat and one upon which five-sixths of the medical staff appear to be in unanimous opposition to the remaining sixth. Moreover, the chairman of the quarterly board of governors is reported as saying that he considered that the members of the staff were quite right in not voting at the weekly board, "otherwise they would have been sitting as judges on their own case." But the chairman of the quarterly board of governors is also the chairman of the weekly board and the meeting of governors was called to adjudicate upon the decision of the weekly board. Therefore the chairman of the meeting of governors practically did the very thing which he praised the medical staff for not doing—namely, sat in judgment on his own case. However, the lay authorities of the hospital have decided against the majority of the staff and in our opinion the staff had better try to settle matters between themselves. It surely ought not to be difficult with the exercise of a little "sweet reasonableness." It is a thousand pities that the work of a beneficent institution such as a hospital should be impeded because the essential members of its *personnel* cannot agree upon a method of procedure.

THE BATTLE OF THE CLUBS.

ANY practitioner who is asked to take the appointment of medical officer to an association of clubs in the district of Holmfirth, Yorkshire, would do well to communicate previously either with Dr. H. Watthews or Dr. H. W. Williams, both of Holmfirth.

THE PREVALENCE OF SMALL-POX.

THE returns of small-pox in London for the past week show the following figures:—On Saturday, April 26th, there were 39 cases notified and removed; on Sunday, the 27th, there were 27 fresh cases; on Monday, the 28th, there were 31 fresh cases; on Tuesday, the 29th, there were 28 fresh cases; and on Wednesday, the 30th, there were 39 fresh cases. In the county of Essex for the week ending April 26th, there were notified 63 cases, making a total of 890 cases throughout the county from Jan. 1st.

THE ST. JOHN AMBULANCE BRIGADE.

WE understand that an association of honorary surgeons of the St. John Ambulance Brigade has been formed, having as its objects: (1) to further civil ambulance work; (2) to aid and advance the interests of the Order of St. John of Jerusalem; (3) to watch the interests of the honorary surgeons; and (4) to promote social intercourse among its members. Circular letters have been sent to all the honorary surgeons throughout England and Wales, and any of these gentlemen who may not have received them are requested to communicate with the honorary secretary, Dr. James J. Marsh, 104, Sloane-street, London, S.W. The first annual meeting will be held at the Hotel Cecil on June 25th, and will be immediately followed by the first annual dinner. The present annual subscription is 2*s.* 6*d.*

THE MANCHESTER AND SALFORD HEALTH ASSOCIATION.

THE jubilee of the Manchester and Salford Health Association falls in the present year and has been celebrated by a congress on sanitary reform which was opened in the Manchester Town Hall on April 24th. The Lord Mayor in welcoming the members on their arrival said that theirs was the oldest sanitary association in the country and that it had given direction and encouragement to the efforts of other towns and societies. The presidential address was delivered by the Bishop of Manchester (the Rev. Dr. Moorhouse) who discussed at considerable length the death-rates of Manchester and Salford, comparing them with those of other places and emphasising the importance of sanitary surroundings as a factor in the moral and physical improvement of the population. At the close of the Bishop's discourse the chair was taken by Professor J. Dixon Mann and the business of the conference commenced with an address delivered by Dr. Arthur Ransome on the history of the association, the preludes to the formation of which were the publication of the report of the Health of Towns Commission in 1842 and the revelations made by the returns of the Registrar-General with respect to the great mortality of most large towns. Sir James Crichton Browne, whom one of the speakers styled the "Chrysostom of the profession," then introduced the subject of light and sanitation in a speech remarkable for its scientific breadth, sustained eloquence, and wealth of impressive phraseology. Naturally enough, he was severe in his condemnation of the window tax which, he said, was instituted in 1696 and continued in force till 1851. It had blighted domestic architecture for 150 years, it had undermined in some degree the physical vigour of the people, and it had accustomed them to dingy dwellings. Sanitary laws were similarly infringed by the modern practice of building houses of inordinate height and by the production of immense volumes of smoke in factories and in various industrial processes. Papers were then read by Dr. Arthur Newsholme on Vital Statistics and by Mr. Horsfall on the Housing Question.

PLAGUE AND RATS ON SHIPBOARD.

A VALUABLE contribution to our knowledge of the transmission and diffusion of plague is provided by the circumstances of an outbreak on board the s.s. *Antillian*. This vessel, a troopship of 3666 tons, left Capetown with a clean bill of health on Feb. 1st, 1901, and entered Sydney Harbour on March 2nd, having no cargo but in shingle ballast and completely fitted for carrying mounted troops; there was a crew of 65 persons in all but there were no passengers and no surgeon. The health officer of the port was informed that all hands were well except a sailor who was thought to be suffering from pleurisy. It was known that plague had occurred at Capetown subsequently to the departure of the *Antillian* and an examination of the patient showed that he suffered from that disease. He was therefore removed to the hospital, where he died on March 3rd, and the vessel was sent to the maritime quarantine station; at the same time inoculation was offered to all hands, but only ten (mostly officers) accepted. During the night of March 11th–12th a man who was a storekeeper on board fell ill with a typical attack of plague from which he was pronounced convalescent on the 31st The bodies of two rats which had been picked up dead on the vessel on March 4th were found to be teeming with plague bacilli. The captain said that there were not many rats on board, but that on Feb. 22nd, the day of the departure of the vessel from Albany, Western Australia, where it had been for 24 hours, 15 carcasses were discovered. At Albany the vessel anchored in the stream and received coal from a lighter which came alongside. Plague broke out immediately afterwards in Western Australia, but there was never any suspicion of the disease in Albany among either the human population or the rats; most of the cases occurred in Perth, 245 miles from Albany but connected with it by rail. At Sydney the *Antillian* was four times fumigated with sulphur, more than three-quarters of a ton having been burnt. The store-rooms, having probably been the resort of rats, were specially treated; they were at different times twice sprayed with corrosive sublimate solution (one in 500) by means of Geneste-Hirscher sprays and were separately fumigated. After repeated searches only 83 dead rats were found and the vessel was released for service on March 15th. In a report on this case made to the State Treasurer Dr. J. Ashburton Thompson, the President of the New South Wales Board of Health, draws attention to the circumstance that plague communicated to the rats which infested a vessel of 3666 tons to the number of about 100 continued among them for 29 days and yet at the end of that term it had killed only a minority of them. From this it may be inferred that length of voyage within the limits common with steamships at the present day does not avoid the risk of infection run by clean ports which are in communication by sea with infected ports. Another fact of even greater practical importance is that a ship may become infected at a port (in the present instance, Capetown) which lay under no suspicion of plague at the time the ship left. Under ordinary circumstances communication of such a ship with any healthy port at which it arrived would be unrestricted, and there is reason to believe that the epidemic at Sydney in 1900 originated in this way.

OVERCROWDED TRAINS.

THE recent disaster to a workmen's train on the Great Eastern Railway at Hackney Downs Junction, having as its result the death of several persons and the maiming and mutilation of others, will serve a useful purpose if it calls public attention effectively to the question of overcrowding railway-carriages. No doubt the inquiry which will follow into the causes of the accident will show to what extent, if any, overcrowding may have been responsible for what happened, and also to what extent, if any, it may have aggravated the injuries and suffering inseparable from so serious an occurrence to a passenger train. The accidents, however, which take place in consequence of the number of passengers travelling by train exceeding altogether the accommodation provided by railway companies, without taking into account such serious catastrophes as that to which we are referring, are very numerous. Hundreds of men and women in and round the metropolis daily risk life and limb in the struggle to obtain standing room in trains that will convey them to or from their work. Should they be successful in entering a compartment they have to travel, perhaps for an hour or two daily, in an atmosphere of the foulest description. The justification of such overcrowding of the train is, presumably, the contention that the workmen's train could not be run without it, except at a loss So much, however, has been done, which to our fathers would have seemed ruinous and impossible, to improve the conditions of travelling for the humbler classes, that we cannot readily admit the want of accommodation in the workmen's train to be a necessity for which no remedy is possible. Our methods of locomotion are just now in a violently transitional state, especially in, and in the vicinity of, crowded centres. Hopeful people, with Mr. H. G. Wells as their prophet, believe that order will soon be evolved from chaos. If this be so, order will be attained by the ruthless confiscation of all machinery found wanting in the ameliorated condition of things. Our railway companies should have it before their eyes that competition is at last putting them on their trial.

THE annual meeting and May dinner of the Aberdeen University Club, London, will be held at the Trocadéro Restaurant on Wednesday, May 21st, at 7 P.M. The chair will be taken by Sir John Anderson, K.C.M.G., and those intending to be present should communicate with the honorary secretaries, Dr James Galloway and Mr. J. Malcolm Bulloch, at 54, Harley-street, W.

THE Prince of Wales, as President of King Edward's Hospital Fund for London, has received from Mrs. Samuel Lewis the first quarterly instalment of the munificent annual subscription of £10,000 which she will give to the fund during her life. This represents the interest on the amount bequeathed to the fund by her husband, in which sum she has a life interest.

THE May dinner of the Edinburgh University Club of London will be held at the Criterion Restaurant on Wednesday, May 7th, at 7.30 P.M., under the chairmanship of His Grace the Duke of Argyll, K.T.

THE governing body of the Jenner Institute of Preventive Medicine has appointed Major Ronald Ross, F.R.S., late I.M.S., to be head of a new department in the Institute at Chelsea.

THE annual general meeting of the Medical Defence Union will be held on Thursday, May 15th, at 5 P.M., at 4, Trafalgar-square, London, W.C., to receive the annual report of the council and the statement of accounts and to transact other business of interest to the union and to the profession at large.

A MEETING of the Anatomical Society of Great Britain and Ireland will be held at the Charing Cross Hospital Medical School, on Friday, May 9th, at 4 P.M.

LORD CROMER'S ANNUAL REPORT ON EGYPT.

LORD CROMER'S annual report on the finances, administration, and condition of Egypt is, as usual, full of interesting and clearly expressed information. Having dealt exhaustively with the affairs of the whole country (exclusive of the Soudan) under 82 distinct headings, his lordship in conclusion feels justified in placing on record two extremely satisfactory deductions: (1) that "the past year was one of steady and normal progress"; and (2) that "in Egypt proper it may be said that the foundations on which the well-being and the material prosperity of a civilised community should rest have been laid." To anyone who was acquainted with Egypt in the bad old times before the British occupation 20 years ago the transformation which has taken place must appear to be well-nigh as miraculous as though our Consul-General had had the control of Aladdin's lamp. It would be impossible to describe the universal betterment more tersely and adequately than Lord Cromer himself does; we therefore append his *ipsissima verba*:—

> It is, of course, obvious that in every department of the State further improvements are both necessary and practicable. But these are, for the most part, matters of administrative detail. So far, at all events, as the purely Egyptian portion of the administration is concerned no radical change of any kind appears to be required. The fiscal system has been placed on a sound footing. The principal irrigation works are either completed or are approaching completion. Means of locomotion, both by rail and road, have been improved and extended. The institution of slavery is virtually defunct. The corvée has been practically abolished. Although both the judicial system and the organisation of the police admit of further improvement it may be said that law and order everywhere reign supreme. The courbash is no longer employed as an instrument of government. The army is efficient and well organised. The abuses which existed under the old recruiting system have been swept away. New prisons and reformatories have been built. The treatment of prisoners is in conformity with the principles generally adopted in Europe. The sick man can be nursed in a well-equipped and well-managed hospital. The lunatic is no longer treated like a wild beast. Means have been provided for enabling the peasantry to shake themselves free from the grip of the money-lenders. A very great impulse has been given to education in all its branches. In a word, all the main features of Western civilisation have been introduced with such adaptations as have been necessitated by local requirements.

Of the 82 sections into which Lord Cromer's report on Egypt proper is divided no fewer than 22 are more or less intimately concerned with medicine and sanitation. Under the heading "Medical Administration," we are told that the number of admissions to the Government hospitals continues to increase, 23,447 persons having been treated as in-patients in 1901 as against 22,572 in 1900; and also that, judging from the steady increment in fees observable every year, it is evident that the native population is beginning to appreciate the advantages of hospital treatment. At Kasr-el-Aini the income under this head has risen from £E349 in 1896 to £E1247 in 1901.

In the course of 1901 two very important modifications of administrative detail were sanctioned. Hitherto the construction and repair of buildings utilised for medical and sanitary purposes have been carried out by the Public Works Department but in future this work is to be done under the orders of the Director-General of the Sanitary Administration, who has been allowed to employ his own staff of engineers and others for the purpose. The second modification deals with the scavenging and watering service of Cairo which, with its entire staff and plant, was once more handed over to the sanitary director from Jan. 1st, 1902, the accompanying grant amounting to £E25,000.

Under the heading "Infectious Diseases" Lord Cromer writes as follows:—

> Independently of plague, 3622 cases and 632 deaths from infectious diseases were notified during 1901, against 4144 cases and 1027 deaths in 1900. Small-pox accounted for 1665 cases and 220 deaths. Cairo was comparatively free from this disease during the year, only 20 cases and four deaths occurring against 172 cases and 41 deaths in 1900. This immunity was, without doubt, due to the very thorough revaccination of a large proportion of the population during 1900. The good results of efficient vaccination in preventing the spread of small-pox cannot be better illustrated than by what took place at Port Said in 1901 when an outbreak of the disease occurred in that town.
>
> The population of Port Said is 47,500, of whom 35,000 are natives and 12,500 Europeans. 174 cases and 56 deaths from small-pox were reported from this town during 1901. Of these 129 cases and 38 deaths occurred among Europeans and 45 cases and 18 deaths among natives. This enormous disproportion was, without doubt, due to the lack of vaccination among the European population. It is possible to enforce vaccination among the native population but among the European, though vaccination is compulsory by the law of the country, it is impossible to enforce it, as the Egyptian Sanitary Department has to depend on the consuls of the various countries for the notification of births in their respective colonies and these notifications are either sent with no information as to the residence of the parents or are not sent at all, so that it is impossible to trace the children and prosecute the parents in the courts if they refuse to have them vaccinated. Over 30,000 of the inhabitants of Port Said were vaccinated between January and June, 1901. After the end of June no further cases occurred.

Lord Cromer commends the above facts and figures to "those who are disposed to doubt the utility and efficacy of vaccination," and adds that small-pox, which was formerly very prevalent in the province of Assouan, especially among the Bisharin Arabs, has been almost entirely stamped out by more efficient vaccination.

With reference to diphtheria Lord Cromer writes:—

> 357 cases of diphtheria occurred in the town of Cairo during 1901, as against 210 certified during 1900. The difficulty of suppressing the ravages caused by this disease arises from the fact that many cases among the native population are not brought to the notice of the sanitary authorities until after death has taken place. In all houses infected with diphtheria and those in contact with them the prophylactic treatment by the injection of anti-diphtheritic serum has been practised on all surviving children where the parents have accepted it. In houses where this treatment has been carried out second cases of the disease have never occurred. It is regrettable that in some cases parents will not accept this treatment for their healthy children who have been more or less in contact with the infection of diphtheria, as without doubt it offers a very real protection against the disease.

It is satisfactory to find that sanitation is making some progress in the villages of Egypt as well as in the towns. During the past year 227 cemeteries were condemned and other sites were selected in lieu of them. "Very few villages now remain," adds Lord Cromer, "in which it will be necessary to change the cemeteries." The work of improving the sanitary condition of the mosques likewise continues steadily. 1179 village mosques were dealt with in 1901, but Pinching Bey, late Major R.A.M.C., Director of the Egyptian Sanitary Department, is unable to report as favourably regarding the *birkets* (ponds) which exist in the neighbourhood of nearly every village and which constitute a danger alike to human beings and to animals. Lord Cromer, however, trusts that "sooner or later it may be possible to deal with this important, but somewhat difficult, subject."

In Egypt a good and pure water-supply is one of the first of needs, for, unfortunately, the Nile—its only source—has from time immemorial been used as a main sewer. Arrangements, we are told, have been made to supply several more provincial towns with good water. Borings have also been made with success in others and the necessary steps have been taken to prevent contamination prior to delivery. At Alexandria new filter-beds are under construction but the new scheme for distribution will not be completed for three years. With the approval of Government the municipality of this seaport has recently raised the sum of £E500,000 which is to be spent on sanitation. In Cairo a system of surface-drainage for the removal of storm water has been completed at a cost of £E20,500, the work having been carried on by night as well as by day, but Lord Cromer makes no mention of the larger scheme for the complete sewerage of the city about which so much was heard a few years ago. It would probably lessen the growing dampness of Cairo if used garden and kitchen water could be removed by these new drains, but, of course, care would have to be taken to prevent the entrance of sewage matter.

Since 1895 a sum of £E21,000 has been spent on alterations and improvements in the only lunatic asylum which Egypt possesses. The accommodation is, however, entirely insufficient and a second asylum is much needed. Only 85 *hashish* patients were admitted in 1901, as against 128 in 1900, the improvement being due to the "campaign" against the importation and use of the drug which has been prosecuted with much vigour.

> The most interesting medical work at present in hand at the asylum (writes Lord Cromer) is the observation of cases of insanity due to, or accompanied by, pellagra. A record of these cases is being published in European scientific journals.

One of the last and most obstinately defended of the strongholds of corruption in Egypt was what is known as the *Wakfs*—or more properly *Ouckaf*—a body of trustees charged with the administration of vast properties which from time to time have been bequeathed for the benefit of charity (including hospitals), religion, and education In 1898 the accounts showed a deficit of no less than £E27,000 but in 1901 there was a revenue of £E245,000 During the five years the aggregate surplus amounted to £E270,000 As Harari Pasha, quoted by Lord Cromer, justly remarks, "These results are worth recording, or else the public, interested in the *wakfs*, may be led to forget the past and think the administration has always existed in its present form" In addition to the public *wakfs* there are also numerous private *wakfs* whereof the beneficiaries now receive the full amounts accruing to them. Too much praise cannot be accorded to the way in which this extremely delicate reform has been carried out. Very large sums have been saved from diversion to improper purposes without the least ruffling of Mohamedan religious feeling

A report on the Soudan, which on this occasion has been compiled by Lord Cromer himself, is included in the publication and there is also a highly interesting memorandum on the plague in 1901 by Pinching Bey

AN ACTUARIAL VIEW OF VACCINATION AND SMALL-POX

ON Monday last, April 28th, at the Institute of Actuaries, Staple Inn Hall, Holborn, a paper by Mr. Arthur Francis Burridge, the secretary of the Equity and Law Life Assurance Society, was read, dealing with vaccination in a manner that is just now of particular interest to the medical profession. Mr C D HIGHAM, President of the Institute of Actuaries, occupied the chair

Mr BURRIDGE commenced by pointing out that the Journal of the institute contained little information on vaccination, only a few brief remarks by Dr S H. Ward in 1860, some paragraphs in a general paper by Mr W H Porter in the same year, and a paper by Dr Sprague in 1877 Starting with the introduction of the practice of inoculation consequent on a letter sent to England by Lady Mary Wortley Montagu in 1717, he then traced the history of vaccination down to the present time, illustrating his remarks with tables and charts conclusively showing that there must be in all civilised countries some other cause in addition to sanitation which had favourably affected small pox mortality The conclusions arrived at in his historical *résumé* were clearly brought out. He found that the diminished mortality from small pox in the various countries dealt with had followed vaccination legislation and that a marked difference appeared since the epidemics of 1870 and 1874 as between those countries which enforced and those which did not enforce vaccination ; and further that in the only country in which revaccination was compulsory—namely, in Prussia—small pox had been practically eradicated. As regards England and Wales the last 50 years he divided into two periods—namely, the period from 1848 to 1870 during which vaccination was compulsory though not strictly enforced, and the period 1871 onwards in which vaccination was more or less compulsory The mortality in the first of these periods fluctuated considerably but showed on the whole a slight downward inclination The second period opened with an epidemic and the figures for 1871 72 were abnormal. The mortality in the following year fell to a low point, and from that time it had fluctuated within much narrower limits Next he found that the decline in mortality had principally affected children under 10 years of age, the influence being less and less felt as the higher age groups were reached, until, for ages above 45 years the mortality from small pox remained at the present day as heavy as it was 50 years ago Mr Burridge next examined the statistics of special communities and classes in which the vaccination condition was ascertainable. The tables and plotted curves dealing with the Sheffield epidemic showed, he said, the very large immunity from attack enjoyed by the vaccinated class as compared with the unvaccinated The gradual approximation of the rates among the two classes as the groups at the higher ages were reached was strikingly shown, as was the very small percentage of fatal attacks among the vaccinated classes. The experience of armies, Mr Burridge pointed out, formed the largest available material, where individuals were under constant supervision and where the vaccination condition was a more or less known factor, while the mere act of vaccination gave no protection unless it was efficient. An examination of the number of marks afforded some guide to the degree of protection, the evidence upon the whole pointing to the conclusion that the greater the number of marks the greater the protection Proceeding to inquire what the operation of the law had effected for vaccination Mr Burridge said that vaccination was made compulsory by the Act of 1853, but its universal practice was not strictly enforced until the passing of the Act of 1871, when it was rendered obligatory on the part of the guardians to appoint vaccination officers to enforce the operation of the law For many years subsequently to the passing of this Act the number of infants unaccounted for with regard to vaccination in the year of birth was about 5 per cent. only, the remaining 95 per cent. having either been reported as successfully vaccinated, as insusceptible of vaccination, as having had small pox, as having died unvaccinated, or as having received certificates of postponement. Since 1883, however, the percentage of infants unaccounted for had, he said, been steadily on the increase, until in 1898 22·9 per cent of children were not finally accounted for The conscientious objection clause had somewhat improved the figure. He attributed the large number of children unaccounted for between the years 1889–96 to the fact that a Royal Commission on Vaccination was sitting during those seven years Mr Burridge concluded his paper with suggestions for increasing the popularity of vaccination and for adding to its efficiency Of these the most important, even from a medical point of view, was that every medical man should be a public vaccinator and should receive a supply of the Government lymph.

The PRESIDENT (Mr Higham), in inviting discussion, said that all present would agree that Mr Burridge had read an excellent paper He did not think that the conscientious objector counted for much, though it was a pity that he had been manufactured He suggested that the present system of penalties should be supplemented by a system of rewards There was no reason why a small fee should not be paid to the man or woman who brought his or her child to be vaccinated soon after birth There were many more objectionable ways of spending public money

Mr WATSON, while agreeing in the main with Mr Burridge's paper, pointed out that available statistics were not complete enough to convince the anti vaccinationist He pleaded for a better understanding of statistics on the part of medical men.

Dr SYMES-THOMPSON thought that the paper would convince all except those who would not be convinced

Mr RYAN regretted that the reader of the paper had made no reference to Dr William Farr and had not given statistics relating to Switzerland since the abolition of compulsory vaccination in 1885.

Mrs. GARRETT ANDERSON spoke of the desirability of educating public opinion as much as possible with regard to this question. No mathematical proof was possible when dealing with human beings, though there was an experiment which would be very cruel—and she did not advocate it—which would approach such a proof If 10 vaccinated and 10 unvaccinated children were allowed to stay in a small pox ward for two or three days she thought that it would prove uncomfortable for the 10 unvaccinated children. With regard to the improvement of the Vaccination Act of 1898 she hoped that the powers at present possessed by boards of guardians would be taken away from them and put into the hands of the health authorities There ought, she considered, to be a better supply of lymph and it should be supplied to the private practitioner Glycerinated lymph, it had been stated, would keep only a week and the private manufacturer could not be expected to destroy stock remaining unsold at the end of seven days In Germany there were 25 State institutions for the manufacture of lymph Considering what a small pox epidemic cost us it was false economy on the part of the Government not to produce an adequate supply of lymph The word "compulsory" was an objectionable one and she suggested that "obligatory" might be better liked by some. If masters would make their employés show their vaccination certificate before hiring them much good would be done.

Mr WARNER reviewed the objections of the conscientious objector

Dr. S. MONCKTON COPEMAN said that his position at the Local Government Board somewhat tied his hands, but he felt that it would be unwise to let a remark made by Mrs. Garrett Anderson, to the effect that glycerinated lymph would only keep for a week, go before the public without correction. It occasionally happened that a batch of lymph was not particularly good, but the Local Government Board took every opportunity to test the lymph before it was distributed, and he had frequently had samples three months, six months, or even a year, old which gave good results. What he suspected Mrs. Garrett Anderson was referring to was the fact that public vaccinators were requested to use the lymph within a week of its being sent out. The reason of that was because it was occasionally found that public vaccinators had been known to leave the lymph in a warm room and in sunlight, two factors which were detrimental to lymph. The supply *certainly did* run short during the great rush in the early part of the year when the demand for lymph was 50 times as great as at other times and the Local Government Board did not feel justified in increasing the laboratories to an extent which would meet a permanent demand of that kind. At the present time it was not intended to supply private practitioners but it was not improbable that the scope of the supply of Government lymph might be increased.

Mr. BURRIDGE, on account of the lateness of the hour, only briefly replied to a vote of thanks.

THE METROPOLITAN WATER-SUPPLY: THE LONDON WATER BILL.

ON April 22nd the Joint Committee of the two Houses of Parliament continued its inquiry into the London Water Bill. At the opening of the proceedings Mr. PEMBER, K.C., stated the position held by the water companies in regard to the Bill. They were "unwilling sellers," and if their undertakings were to be transferred to a public body they desired that the terms of that transfer should be in their judgment, "fair and reasonable," which, being interpreted, means that they wished to get as much as possible. The case for the Bill was conducted with considerable reserve by Mr. RICKARDS, K C., who is well acquainted with the subject and who has published a very useful little book on the London water-supply.

Mr. C. PERRIN, M.I.C.E , the Water Commissioner to the Local Government Board, first gave evidence as to the districts of supply of the water companies, the population of each district and its rateable value, and the present boundaries of "Water London."

Mr. RICKARDS then said that he did not propose to tender further evidence concerning the question of transfer and that he relied on the various Royal Commissions on the London water-supply. Counsel for the water companies did not entirely approve of this method of proceeding, but, in reply to Sir E. CLARKE, K.C., and Mr. PEMBER, the CHAIRMAN (Lord Balfour of Burleigh) held that the water companies would not be damaged by the absence of further evidence.

The counsel for the Bill then stated that they did not propose to tender evidence on the "appointed day" on which under a provision of the Bill the undertakings of the companies should be taken over by the proposed Water Board, for the constitution of which the Bill also provided. Lord BALFOUR held, however, that the limit of time laid down in the Bill was not entirely a matter for argument but was to some extent also a question of fact. In consequence of this decision Mr. J. LITHIBY, assistant secretary to the Local Government Board, was called to state why that department proposed the appointed day. The proposal was that whether the purchase price were then ascertained and paid or not the undertakings of the companies should vest in the Water Board on the appointed day. The arguments in favour of that proposal were that as it would probably be necessary that the value of the undertakings should be settled by arbitration and that as, moreover, arbitration was not an expeditious proceeding if a day were not definitely appointed on which the Water Board should take over its duties it might happen that the arbitration would hinder the board from beginning its work, and that it was likely that when the companies definitely knew that their businesses were to be transferred their interest in managing them for the benefit of their customers would be less keen. The arrangements for the transfer would occupy some years, and it might be seriously detrimental to the water consumers if there were no authority exercising adequate control over the supply of water during that period. The proceedings of the Water Board would be seriously hampered if it did not take over its duties on a definite day. The day which it was proposed should be that on which the duties were to be transferred to the Board was 12 months after June 24th, 1903. Before that date the companies would have ample time to "prepare their cases" and to get them settled. Mr. Lithiby said that he had had no experience of managing a water company and he added that the secretary and the assistant secretaries advised the Local Government Board on the London water question and that it had been his function to advise in this particular case.

The cause of the objection to the appointment of a particular day for taking over the water companies' undertakings can be readily understood from the cross-examination of this witness by Mr. PEMBER, who showed very clearly the fears of the water companies as to the effect of some of the evidence which might be tendered in the arbitration cases. *On which side*, he asked, would the engineer of a particular company, whose undertaking had already been transferred, give evidence—for the purchaser or for the vendor? Lord BALFOUR said that he presumed that the engineer would tell the truth and this suggestion was received with laughter.

The financial proposals of the Bill were supported by Mr. BANBURY, M.P., trustee and manager of the London Stock Exchange. Mr. Banbury said that he had not been consulted beforehand by the Local Government Board and that he had had nothing to do with the drafting of the Bill. The suggested mode of payment to the water companies by means of water stock was really due to Mr. Banbury's ingenuity and it was explained by him with great clearness at the thirtieth sitting of the Llandaff Commission which took place on July 18th, 1898.

In regard to the transference of the water compani undertakings to the Water Board on a definitely appoint day Mr. JAMES MANSERGH at a sitting held on April 2 gave evidence in support of the Bill and Mr. GEORGE HILL gave evidence against the proposition. Both th gentlemen are past presidents of the Institute of Ci Engineers; the former was employed by the Local Gove ment Board, the latter by some of the water compani Mr. HAYWARD, the controller of the London County Counc gave evidence against the financial arrangements propos in the Bill. The engineer employed by the Local Gover ment Board said that he knew personally all the enginee employed by the metropolitan water companies; they we all gentlemen and would act as such. They would give t same evidence on the facts whether they were acting on t one side or the other; but—and this is the point on which strong light is thrown on the ethics of expert evidence "when it came to giving an opinion upon value then the evidence should be as a witness for the company" (*vi Times* report).

The Joint Committee met on April 29th, when the eviden of Mr. MACKINNON WOOD, chairman of the Water Con mittee of the London County Council, was taken.

The Joint Committee met again on April 30th, when M MACKINNON WOOD was cross-examined. The evidence w taken of Mr. SHAW-LEFEVRE, late President of the Loc Government Board, and of Mr. G. F. DEACON, late chi engineer to the Corporation of Liverpool. The evidence both was condemnatory of the Bill, and after an hour deliberation in private the Joint Committee decided to alt the constitution of the proposed Board by deleting the repr sentation of the metropolitan boroughs and of the urba districts and boroughs in the counties of Essex, Kent Middlesex, and Surrey.

HEALTH OF MALMESBURY.—At the meeting o the Malmesbury Town Council held on April 8th the medica officer of health (Mr. C. W. Pitt) presented his annual repor for 1901. This stated that during the year 69 births had bee registered, giving a rate of 23 per 1000. The death numbered 33 (18 less than in 1900), corresponding to a rat of 11 per 1000.

Looking Back.

FROM

THE LANCET, *SATURDAY, MAY 1, 1824.*

LEPROSY.

The following description of the species of leprosy commonly met with in India, is from the interesting work entitled—*Sketches in India*, written by Mr HUGGINS, late an indigo planter in the district of Tirrhoot:—

"A person attacked with the species of leprosy prevalent in India is bloated in his face; his forehead, nose, lips and ears swell out; his nostrils expand; his eyes appear sunk and very fiery; the tone of his voice is altered to a loud and somewhat nasal sound; no eruptions appear upon his body but his skin is hard, parched, and dry, having entirely lost its softness and moisture. About the shoulders he appears tight and contracted; his knees are stiff and motions constrained; the hairs fall off him, or are seen in their stunted stalks, dried up from want of wholesome nourishment; his breath is fœtid, his perspiration stopped, or if it flows at all is rank and stinking; he complains of *excessive internal heat, cannot bear exposure to the sun, and is* irregular in his discharges, the digestive organs performing their functions very imperfectly; there is a certain numbness seizes all his faculties, so that his sensations of pleasure and pain are considerably impaired; and lepers of this kind have no excessive propensity to venery after the disease appears, although they may have had it before. It is a common opinion that people seized with this malady are of a warm and amorous temperament; but when a person is seized with leprosy, the pleasure derived from such indulgencies, and the capacity for them are in a great measure annulled. After these primary symptoms, when the disease has become inveterate, the leper's fingers are gradually eaten away, and drop off at the joints; his toes are affected in a similar manner sores break out about his ancles and wrists. During the progress of these cancerous attacks no pain is endured by the leper, owing to that numbness which I have already stated as pervading his system whilst the disease gradually proceeds ulcerating his flesh, and dissolving his joints, till the vitals become affected In the last stage his flesh gapes with long sores, his mouth, nose and brain dissolve before the leprous poison, till death happily relieves him from such accumulated miseries Some fakirs profess to cure this disease, if applied to at an early stage of it; and I have *myself known men healed by them* *To effect* a cure these men administer a root procured from Nepaul, which causes copious salivation; they also put the patient on a regimen, forbid him the use of salt and sexual cohabitation, and the lepers who recover generally abstain from these during the remainder of their lives"

THE ROYAL ACADEMY.

THE 134th exhibition of the Royal Academy of Arts which will be open to the public on *May* 5th is an average show That is to say, there are good pictures and mediocre pictures, but there is no work like the famous "Ascher Wertheimer" of Mr Sargent exhibited in 1898. That accomplished artist sends eight portraits, of which perhaps the best are (157) "Alfred Wertheimer, Esq," and (323) "The Duchess of Portland" The painting of the jewels in the last-named is comparable to that of Titian in the "Family of Darius." To our thinking, however, by far the best portrait in the exhibition is (202) "Lady Marjorie Manners" by Mr. Shannon. Both colour and quality are beautiful and the way in which the various shades of black are managed is worthy of all praise

Of portraits which have a more or less medical interest we must mention (134) "The Right Honourable the Lord Mayor of London," Sir Joseph Dimsdale, M P, by Mr A S. Cope; (244) an admirable picture of "Lord Kelvin," by Mr Ouless; (291) "Professor J B Pettigrew," also by Mr Ouless; and (788) a very good likeness of Surgeon General Jameson by Mr. W R. Symonds A clever portrait is (45) "Miss Gertrude Bowles," by Mr Mouat Loudan Of figure studies Mr H J Draper in (23) "A Deep-sea Idyll" shows his usual mastery in anatomical drawing and flesh painting, while good anatomical drawing and modelling triumphing over difficulties of position are to be found in (110) "Many Waters cannot Quench Love," by St. George Hare, and in (149) "Storm Nymphs," by the President. In (295) "The Plague," Mr John Collier has painted a gruesome subject with great skill His dead lady looks really dead. we have never seen the absolutely lacklustre eye of a corpse represented more truthfully Of other pictures Mr Charles Sims's "The Top o' the Hill" (24) is full of breeze and light and atmosphere, while Mr. W. Hatherell in his "Gleaners Waiting for the Last Load" (92) sends a clever study of a low evening lighted landscape In the large room (160) "A Tanagraean Pastoral," by Mr. G H. Boughton, exhibits all the painter's well-known grace and delicacy of handling, while special mention must be made of (166) "The Isle of Avalon," by Mr. J. W. North; of (167) "Tucking the Rick," by Mr La *Thangue*, of Mr *Melton Fisher's* charming picture (179) "The Mirror"; of (191) Mr Hook's "Home from the Marshes," wherein we grieve to state that the returning sportsman has shot a heron, of (198) by Mr. W J Donne, being a very original presentment of "The Chalk Pit, Merstham"; and (201) a perfect little gem by Sir L. Alma Tadema, "Caracalla." Mr George Clausen, in (648) "The Rickyard: a Winter Idyll," gives with his usual skill the effect of the cold wintry sunshine. *Of* the sculpture we may mention (1600) "Fairy Tales," a pretty little statuette, by Mr F M Taubman; (1609) Mr Brock's statue of Gladstone, (1617) Mr Swan's wonderful representation of a wounded leopard. It is transfixed by an arrow, at which it is tugging in a vain effort to extract the missile The late Mr Onslow Ford has several examples of his art, the most noticeable of which is (1723) "Snowdrift"; *another (1694), a silver and ivory group,* "*St. George and* the Dragon," is a piece of real handicraft. St. George is standing on the dying dragon and he is habited in one of those wonderful petticoated suits of armour which, although they look all right when the wearer is on horseback, are not suitable to a dismounted man. Of the water-colours we have only space to refer to Mr Goodwin's exquisite "Amalfi" (978).

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Bath Urban District—We are glad to learn from the current annual report of Dr W. H. Symons that the criticisms which we published in our columns in October, 1898, as to sanitary arrangements at the Royal Mineral Water Hospital at Bath have resulted in an enormous improvement in the condition of the institution. The general sanitary *arrangements are now,* Dr Symons *states,* "*models of* applied science." This institution was founded in 1737 with the view of gratuitously extending to the poor of the United Kingdom the benefits of the local hot springs Dr Symons has gone very thoroughly into the distribution of tuberculosis in Bath, and he finds that during the last 32 years there have been in some streets no deaths from this disease, whereas in others the deaths have been numerous. In one street he found as many as 52 deaths and as an instance of the diminishing number of deaths from phthisis in one selected locality of the city the figures by decades have been worked out. In 1866-75 there were 34 deaths and in the next decade there were 31 In the five years 1886-90 improvements were made and during this period there were but 11 deaths From 1891 to 1900 there were in the same area but five deaths from this disease In connexion with the control of phthisis in Bath it may be mentioned that the Corporation has contributed £500 towards the erection of the Winsley Sanatorium for consumptive patients and an annual subscription, to provide two beds, of £130

Croydon Rural District—The Croydon sewage farm, which would appear to be situated in or near this district, gave rise to serious complaints during the past year and we are glad to hear that the sewage is now to be further treated Diphtheria has been very prevalent in a locality known as Beddington Corner, *which is bounded on one side by the* Croydon sewage farm and on the other by the polluted Wandle river The soil of the Corner is water-logged and Mr C M. Fegen, the medical officer of health of the district under consideration, is evidently inclined to ascribe to the topographical conditions of the Corner some share in the production of diphtheria, even if such share be one of predisposition only The district council provides antitoxin and opportunities for bacteriological examinations for the medical practitioners of the district. The foul condition of the Wandle remains unabated, but the several district councils morally involved have conferred together with a view to purify the stream.

Correspondence.

"Audi alteram partem."

THE MIDWIVES BILL, 1902.

To the Editors of THE LANCET.

SIRS,—Having recently looked up the Home Office returns of coroners in connexion with inquests upon the newly born, I was astonished at the number of cases in which a verdict of murder was actually returned. It is a matter of common knowledge that juries will only return such verdicts in exceptionally bad cases, so I think that the following figures furnish food for comment. In 1900 there were 614 inquests held upon the newly born out of a total of 37,076 inquests held upon persons of all ages. At inquests held upon the former there were no less than 35 verdicts of wilful murder, whilst at those held upon the latter there were only 145 such verdicts. The rate per 1000 inquests held upon the newly born of verdicts of murder works out at 57, whilst the rate of inquests held upon all other cases works out at 3·8. Comparing private experience of the number of still-born children with the approximate knowledge of the number which are said to be still-born, no just proportion can be found. It is therefore, perhaps, more than a matter of mere suspicion that the amount of infanticide in the country is very considerable and very disgraceful. Unfortunately, the newly born, whose very dependence upon others should excite commiseration and pity, have no incorporated society to protect their interests; they are therefore left out of consideration when influential persons are busy with legislation.

I now ask the question: Does the Bill for the Registration of Midwives at present before Parliament do anything for the protection of the lives of the newly born? Does it not, in reality, render it more easy for those mothers who desire the death of their children to have the deaths procured with less chance of discovery, subsequent inquiry, and perhaps punishment? I say perhaps, for it must be well known that any chance of punishment in these cases is a remote one. It appears to me that the Bill in its present condition is one which contains elements of great danger. I do not myself see how it can be amended, for it is radically unsound. The medical profession will, I venture to believe, be well advised if it makes no efforts to amend it, but leaves its rejection to the good sense of the House of Commons.

I am, Sirs, yours faithfully,

Hatfield, April 28th, 1902. LOVELL DRAGE.

To the Editors of THE LANCET.

SIRS,—I have been requested by the council of the Medical Provident League to ask your permission to express in your widely read columns their collective opinions concerning the present Midwives Bill. They would studiously avoid the imputation of any unworthy motives and feel confident that those who have promoted this legislation—however mistaken they may be—must have been actuated by the best intentions. It is to be hoped therefore that any discussion which takes place upon this subject may be conducted in that spirit of courtesy and fair play which men of all opinions can appreciate.

1. It is believed that general practitioners, owing to their over-busy lives, cannot have had the leisure or opportunity to study this Bill—that they cannot have realised how deeply detrimental such legislation must be both to themselves and to the public—or that they would have taken the most active steps to secure its defeat. Instead of which, week follows week, the matter is scarcely referred to in the press, and there appears to be no organised opposition to the Bill.

2. No one can understand so fully as the medical profession the injury which ignorant midwives can work. But it can be proved that the extent of the evil has been greatly exaggerated, and, moreover, that it is being diminished year by year by the efforts of our profession. The often-repeated argument that because midwives have always existed so they must always continue to exist must appear ridiculous to those who are aware that many races and species have become extinct in the past, and that one of nature's most inexorable laws decrees the extermination of the unfit It is submitted that even if midwives—and other plagues—were necessary evils at the time of Moses they can only be regarded as septic anachronisms in the twentieth century. And, as a demonstrable fact, midwives are rapidly dying out in England; their place is being taken by more or less well-trained obstetric nurses. The advocates of the registration of midwives have studiously avoided any reference to the striking fact that last year out of 4,536,000 people in the county of London there were only 366 midwives, and of these five were over 75 years of age and no less than 83 were more than 55 years old. It may confidently be predicted that the census returns for the rest of England will show similar figures. It is submitted, then, that there is no need for special legislation for such a small and diminishing number of workers.

3. It has been asserted that in those countries in which midwives are registered the mortality in childbirth is much higher than in this country. Accurate and recent statistics on this point would be very valuable.

4. The essential feature of the present Midwives Bill is that it legalises a new order of independent practitioners of midwifery, recognised and supported by the State in their practice. Putting aside all the specious sophistry and special pleading which has darkened counsel on this matter, what does this mean? Simply that the midwife, after some three months' work and at a cost of some £15, would be placed by Parliament precisely on the same level in midwifery practice as the medical practitioner who has devoted five years and has paid probably £1000 for his education. It is mere futile foolishness to pretend that she will not enter at once into active competition with the general practitioner, or to imagine that she will carefully confine her attention to the poorer classes, or to expect that she will refrain from practising medicine as well as midwifery. No power on earth could prevent her from doing any one of these things. She will be a registered practitioner and the public will as eagerly swallow her pretensions as they now accept in blind faith the potency of anything else to which the Government stamp is affixed. It is submitted that the first and greatest effect of this legislation would be to flood the country with more or less well-educated women only too eager to avail themselves of the opportunity of becoming licensed quacks.

5. It is the danger to the public rather than the damage to individual practitioners which will most appeal to our self-sacrificing profession. So it is submitted that to place a government stamp of efficiency upon the existing inefficient, decadent midwife would be a cruel delusion and a snare to the poorer classes. It would be the more unjustifiable because Parliament in 1886 insisted upon an infinitely higher standard for medical men—that is to say, for the protection of the richer classes of society. The last Medical Act ordained that no practitioner should be registered unless proficient in medicine and surgery as well as in midwifery. It is a truism that parturition involves dangers and results which require a complete knowledge of medicine and surgery to combat successfully. Yet Parliament is being asked to guarantee to the ignorant poor the efficiency of midwives who know very little of obstetrics and nothing whatever of the other sciences. Are the lives and safety of poor women of less account than those of the rich? But Parliament has been gravely assured that the medical profession approves of this Bill and the absence of all opposition from us has naturally afforded support to the statement. The second reading of the Bill was taken without a division. The Bill has passed through committee almost unaltered—certainly without one real safeguard being added. Is it possible that the profession will permit it to pass without a single protest?

6. Not only is the principle of this Bill bad, its details are ridiculous. The whole demand for legislation is based on the alleged need of supervising midwives. Yet this supervision is gravely placed in the hands of borough or county councils—that is to say, of worthy gentlemen engaged for the most part in commercial or agricultural pursuits and who must be entirely ignorant of midwifery. Yet they are to be made the judges concerning charges of malpraxis or misconduct on the part of the midwives in their district! It is further submitted that no medical man is likely to take upon himself the thankless and most invidious task of making or supporting a charge of malpraxis or misconduct against a midwife, and who else could or would do so? In brief, it is submitted that the so-called supervision of midwives would inevitably become a Gilbertian farce, and that the midwife would be the most free and independent practitioner in these happy islands.

7. It is being said that opposition is hopeless. The Medical Provident League declines to adopt so invertebrate an attitude. It only comes forward at this juncture because no

other body is apparently moving in the matter and because it realises the very grave public and professional dangers involved in this legislation. But the league will not court failure by taking any action without adequate support. The crisis is acute and demands the most active work and assistance from everyone opposed to this Bill. If at least 500 practitioners will promise their help and a small subscription each towards the necessary expenses, the Medical Provident League will contribute £10; I will give the same amount; other donations will be forthcoming; and opposition shall be organised. But it is already the eleventh hour and if anything is to be done it must be done *immediately*. It is therefore suggested that those who are opposed to this legislation and who will help to prevent it if possible should write *at once* as follows:—

> I will give my active assistance in opposing the Midwives Bill.
> I inclose postal order (or cheque) towards the expenses.
> My Member of Parliament is ———.
> And I also personally know ——— M.P.

with signature and address very clearly written.

This may be sent either to the Secretary, Medical *Provident League, 11, Adam-street, Strand, W.C., or to*

Your obedient servant,
BEDFORD FENWICK.

20, Upper Wimpole-street, London, W., April 19th, 1902.

THE CASE OF DR. W. T. LAW.

To the Editors of THE LANCET.

SIRS,—May I be allowed to direct the kind attention of your readers to a meeting of friends and sympathisers of Dr W. T. Law which will be held at the King's Hall, Holborn Restaurant, W.C, on Friday afternoon, May 9th, 1902, at 2 o'clock?

I *trust that your excellent leading article on Forsythe v.* Law, which appeared in THE LANCET of March 8th, 1902, p. 680, was duly read and weighed by your numerous readers. It begins by stating that: "It has seldom been our duty to comment on a more painful case," *and at the close these words occur: "Had Dr.* Law rendered his services over a term of years for gain and profit—which is not customary when the patient is a nurse—there might have been more room for criticism, but what are the facts? He gave freely of his time, his skill, and his kind-heartedness for no other reward than the satisfaction of feeling that he was discharging a charitable office with the hope of alleviating human suffering. He acted the good Samaritan—not wisely, perhaps, but too well—and what was his reward? Scorn and contumely were heaped upon him by some who were and are to be pitied and by others who deserve severest blame. He will have the consolation which his merits deserve, given unstintedly by his professional brethren and by a generous and just public opinion. His legal and moral acquittal was complete."

In consequence of the poverty of the plaintiff Dr. Law will have to defray his own heavy expenses and as he is not a wealthy man, as is erroneously considered, there will be ample scope for the display of practical sympathy, and for this object the meeting will be held. Sir Samuel Wilks, Bart., Sir Henry Thompson, Bart., the President of the Royal College of Physicians of London—viz., Sir William Selby Church, Bart.—and many other distinguished and esteemed members of the medical profession have shown their sympathy for Dr. Law. Unfortunately, Dr. Law was not a member of either of the medical defence societies, but I may state for the information of the gentlemen who blame him for not being so that they cannot do better than take a lesson of charity from the magnanimity displayed by the former presidents of the Medical Defence Union—viz., Dr W. S. A. Griffith and Mr. Victor Horsley—who already with others have kindly contributed. I am anxious to be able to announce subscriptions at the meeting from members of a noble and generous profession which will be a credit to the profession itself and to the satisfaction and delight of him who is said to have shown unwise benevolence. In this hard, cold, calculating world it is not usual to meet with men who display an excess of benevolence either in thought or deed. When such a one is found let us treat him as he richly deserves

Mr. John Langton writes to me and says: "I hope the profession will show by their gifts that they have solidarity with their professional brethren in time of trouble." I shall be glad to receive and acknowledge any contributions that may be sent on behalf of Dr. W. T. Law. Postal orders or cheques should be crossed "Law Fund, London and County Bank, Holborn." I am, Sirs, yours faithfully,
RICHARD PARAMORE.

2, Gordon-square, W.C., April 28th, 1902.

TRAUMATIC DISLOCATION OF THE CRYSTALLINE LENS.

To the Editors of THE LANCET.

SIRS,—The perusal of Mr. S. Stephenson's interesting paper on Spontaneous Cure of Senile Cataract in THE LANCET of April 26th (p. 1175), reminds me of a case of dislocation of the crystalline lens that came under my care when on the medical staff of Hanwell Asylum The patient, a healthy young woman suffering from mania, received a violent blow on the eye from another patient in the same ward. I saw her directly afterwards and found a transverse rent in the cornea and the lens lying on her cheek. I treated the injury precisely on the plan adopted after the usual operation for cataract, and at the end of a week, on removing the pad and bandage, I was pleased to find the wound in the cornea perfectly united and the patient recovered her normal vision without the least bad symptom. The case was interesting as showing the immunity with which the eye can sustain a severe injury and the facility of recovery under very simple treatment.

I am, Sirs, yours faithfully,
Shanklin, I.W., April 26th, 1902. J. HAWKES, M D. St. And.

TREATMENT OF CHRONIC HEART DISEASE BY RESISTED EXERCISES, OR THE SO-CALLED "SCHOTT" OR "NAUHEIM" TREATMENT.

To the Editors of THE LANCET.

SIRS,—Lest there should be any misunderstanding as to the latter part of the title to my letter, I should like to point out, as has been done before,[1] that the treatment of heart disease by resisted exercises was carried out in Sweden before the Drs. Schott were born and that they merely adopted the Swedish method and combined it with the Nauheim baths. But great thanks are nevertheless due to the Drs. Schott for bringing the treatment prominently before the profession and before the world at large. There are few forms of chronic heart disease in which the treatment fails to afford relief, for if due care be taken even the most serious forms can be dealt with with advantage.

The Nauheim waters are supposed to do good by virtue of the free carbonic acid gas which they contain. The gas keeps on bubbling up through the water and is said to stimulate the cutaneous nerve-endings and reflexly the central nervous system. The Nauheim baths can very easily be prepared artificially with the help of Sandow's effervescing powders and tablets. A mild non-carbonated bath is prepared as follows. In 50 gallons of water at 93° F. four and a half pounds of Nauheim salt are dissolved; three minutes before the bath is to be used one packet of Sandow's effervescing powders is added and stirred and two of his effervescing tablets are placed on the bottom of the bath. The temperature of the water should be 91° F when ready for use. A medium non-carbonated bath contains six and a half pounds of Nauheim salt, a strong non-carbonated bath 10 pounds of the salt. A mild carbonated bath is prepared in a similar way except that four packets of Sandow's powders are added and eight of his tablets placed along the bottom of the bath It contains four and a half pounds of Nauheim salt. A medium carbonated bath contains six and a half pounds and a strong bath 10 pounds of the salt. The duration of the bath should be 10 minutes, increased to 12 and 15 minutes. The bathroom must be well ventilated and the patient after the bath wrapped in a large warm Turkish towel-sheet and dried He should rest lying down for one hour after dressing The bath itself should be either exceedingly well coated with enamel paint, or, still better, be a porcelain or wooden one, as the acid is apt to corrode a metal bath.

---

[1] THE LANCET, Dec. 22nd, 1894, p. 1515.

Having thus very briefly considered the baths we now come to what may be looked upon as the most important part of the treatment—viz., the resisted exercises. The great principle underlying the treatment is to diminish the peripheral resistance to the onward flow of blood and so to make it easier for the heart to perform its work. There are three ways in which this can be done by exercises: (1) by acting on the muscular system; (2) by acting on the respiratory system; (3) by acting on the digestive system.

1. Let us consider what takes place when a muscle is at work. It alternately contracts and relaxes. When a muscle contracts it hardens; the intra-muscular and intra-fascicular blood- and lymph-vessels become squeezed, the fluid is driven out, and owing to the valves which are placed in the veins and lymphatics the fluid is driven towards the heart. This causes a relative fluid-emptiness in the muscle, so that when it relaxes a suction is created drawing the blood towards and into the muscle and away from the heart. Each muscle may, indeed, be looked upon as an *additional heart.* As the heart itself is the great central pump in the body, so is each individual skeletal muscle a peripheral pump which by alternately contracting and dilating pumps the blood onwards. If a single muscle were to be thus acted upon the result might be infinitesimal, but when groups of muscles, say of a limb, are made alternately to contract and relax, the influence becomes important. The fact that muscular contractions really do have a marked effect can be demonstrated by examining the pulse; for whereas the pulse before the exercises may be irregular and quick the almost invariable condition found after exercising is a slower and more regular pulse-rate. I have seen instances where there has been a difference of 20 beats a minute before and after exercising. Besides thus mechanicaly helping on the blood-stream, a more remote result is that waste products and exudations with which the muscles probably are infiltrated are cleared away and that the metabolism becomes more active. It is easy, then, to understand why resisted exercises should be helpful in heart disease. An over-full and dilated heart struggling to contract and to drive the blood onward against great peripheral resistance finds its work eased and feels itself able to perform its function with less output of energy, the result of which is that its action becomes slower and more regular. This result may not last long to begin with—perhaps a couple of hours—but by persevering with the treatment day by day for some time it cannot but permanently improve and strengthen the diseased organ. The physiological effect of resisted muscular exercises on an over-full and dilated heart is very much the same as the effect of emptying an over-distended bladder. The analogy is complete, for are they not both hollow muscular organs?

2. By acting on the respiratory system. It is well known that during an inspiration the large veins in the chest dilate, as do also the cardiac auricles. A suction action is thus established the effect of which is to draw the blood away from the periphery towards the heart. But besides this, by alternately filling and emptying the lungs of air by deep inspirations and expirations the circulation through the pulmonary capillaries and vessels is very much facilitated, for when an air-vesicle dilates during inspiration and resiles during expiration the capillaries in the vesicular walls are alternately put on the stretch and contracted, and this tends strongly to relieve any congestion which may be, and often is, present in the lungs in chronic heart disease. There is yet another way in which respiratory exercises are beneficial—viz , by ensuring a more thorough aeration and oxygenation of the blood, for thus more blood is made to course through the pulmonary circulatory system in any given time.

3. By acting on the digestive system. A common symptom in patients suffering from chronic cardiac disease is irregularities in the performance of the abdominal organs, not—at least in the earlier stages—owing to any actual local lesion, but as the result of the sluggish manner in which the circulation is carried on. Thus we get a congestion of all the abdominal viscera, which shows itself in a deficient secretion of the liver, the stomach, the pancreas, and the bowels, and in the presence of albumin in the urine. The *raison d'être* of the treatment is forcibly shown here. The passive congestion just mentioned offers a considerable resistance to the flow of blood towards the heart, thus rendering the backward pressure extremely felt by an enfeebled organ. An improvement is brought about indirectly by acting on the muscular and respiratory systems, as I have already endeavoured to show, and directly by stimulating and kneading the abdominal viscera through the abdominal walls. *Ubi stimulus ibi affluxus*, or wherever there is a demand for energy thither does the blood flow. The circulation in the abdominal viscera becomes roused, there is a demand for fresh blood, the used-up blood is moved on, greater activity takes place in the various abdominal organs, and the bowels, the liver, the stomach, and the kidneys take on a healthier physiological action.

When writing a movement prescription, then, attention should be directed towards these three systems and a typical prescription would be very much as follows: (1) Arm exercises, (2) respiratory exercise, (3) leg exercises, (4) respiratory exercise, (5) trunk exercises, (6) kneading of the abdominal viscera, (7) respiratory exercise. During the performance of the exercises—which should be given slowly—the pulse should be carefully watched, as should also the patient's respirations, for the slightest evidence of distress, either cardiac or respiratory, must be taken as an indication that a certain exercise may be too strong or unsuitable. It is well that the patient should rest in the most comfortable position for an hour after each treatment, which should occupy about half an hour each time.

Let me, in conclusion, urge members of the medical profession to take up this treatment personally, instead of leaving it in the hands of nurses and assistants. It is becoming more and more recognised what a powerful therapeutic agent for good or evil this treatment is, not only in heart disease, but in many chronic complaints, and it is but right that it should be in the hands of the profession. Then, and then only, will it take its due place in the long list of the various methods of treatment.—I am, Sirs, yours faithfully,

OTTO HOLST, M.R.C.S. Eng., L.R.C.P. Lond.

Eastbourne, April 28th, 1902.

OPERATION FOR SUSPECTED STONE IN THE KIDNEY.

To the Editors of THE LANCET.

SIRS,—In reading the interesting series of cases of Operation for Suspected Stone in the Kidney and the clinica remarks on them published by Mr. Edmund Owen i THE LANCET of April 19th, p. 1105, I am reminded of case that was under my care in the York County Hospita in 1900.

The patient was a man, about 30 years of age, who fo some time before I saw him had been suffering from pai over the right kidney with frequent attacks of hæmaturi and had also passed several small pieces of uric acid calculi. As the pain increased in severity and frequency I cut down upon the right kidney, turned it out, and punctured it in five or six places, but I failed to detect any stone. The kidney was replaced; the wound healed up and since then the patient has been entirely free from pain and hæmaturia. He is now in the South of England and I heard of him a few weeks ago, the report being to the effect that he had been entirely free from all his old symptoms since the operation, that he had put on flesh, and that he felt better than he had done for years. Is it possible that the various punctures may have relieved tension and so produced amelioration of his symptoms?

I am, Sirs, yours faithfully,

WILLIAM H. JALLAND, F.R.C.S. Eng.

York, April 22nd, 1902.

To the Editors of THE LANCET.

SIRS,—Few surgeons will, I think, dissent from the views so ably expressed by Mr. E. Owen in your issue of April 19th, p. 1105. It seems, however, unnecessary to refuse assistance from the x rays through fear of one's judgment being unduly influenced. In a woman on whom I operated a fortnight ago the only indications of calculus were persistent pain in the left loin, from which she had suffered daily for four years, and the occasional presence of a trace of albumin in the urine. A series of excellent radiographs taken by Mr. W. J. D. Bromley, the senior house surgeon at the Lancaster Royal Infirmary, utterly failed to indicate the presence of a stone; yet from the pelvis of this kidney I removed an *oxalate* calculus weighing 48 grains.

The two cases first mentioned by Mr. Owen seem to present little difficulty in diagnosis. Both the subjects were young men who suffered from typical attacks of renal colic accompanied by albuminuria. The only reasonable ground of doubt appears to have been the absence of hæmaturia.

Blood is often absent from the urine in these cases and, moreover, is often overlooked when present. One of my former teachers used to advise his patients to patronise a certain line of omnibuses which were famed for their rigid springs and also for the rugged roads that they traversed. After this he had the urine which was passed during the following 24 hours collected in a conical vessel. An examination of the deposit very rarely failed to detect blood-cells. I believe that attacks of "colic" are only present in a minority of cases of stone in the kidney In many the pain is constant and although subject to exacerbations—which, however, are not paroxysmal in nature—is unaccompanied by sickness or hæmaturia. Increased frequency of micturition is common, but as it also occurs in many other conditions is not of great value as a diagnostic sign. Any reaction to Mr Jordan Lloyd's test is in my experience exceptional

And now as regards two points in the technique of the operation We are frequently told that it is advisable to plug the wound in the kidney I fancy that most surgeons have now discarded this practice. The kidney substance is best brought together by mattress sutures No urine exudes and no drainage either of the kidney or the outer wound is required In reference to the site of the incision into the kidney the experience of those who have used that advocated by Brödel would be of great value. I used it in a recent case but cannot say that I noticed any marked diminution in the amount of bleeding

I am, Sirs, yours faithfully,
Lancaster, April 21st, 1902. A. STANLEY BARLING

THE ROYAL NAVY MEDICAL SERVICE.

To the Editors of THE LANCET.

SIRS,—In the regulations in connexion with the above recently issued by the Admiralty it is stated that early promotion to the rank of staff-surgeon may be granted to those surgeons who before entry held the post of house surgeon to a civil hospital. Would it not be better that a naval surgeon should be allowed to hold a house surgeoncy for six months at his hospital at any time within 12 months of his entering the service, provided he could obtain nomination for such a post, his time and pay counting during such house surgeoncy? At present candidates are deterred from seeking the post of house surgeon before entering the service on account of the loss of time and seniority it would entail. If they were to be permitted to hold such a post after entering it would be for the benefit of the service and would induce the best class of men to join. The candidate who takes his house surgeoncy before entry will always run the risk of finding himself junior in the service to his junior in experience.

There is a further rule requiring naval surgeons to undergo a post-graduate course of three months' duration at a metropolitan hospital once in every eight years, receiving full pay, lodging, and provision allowance, &c., but being required to pay himself the necessary fees for such a course. The rule concludes by stating that the officer will be required to produce separate certificates of efficient attendance in the following: (1) medical and surgical practice of a hospital, (2) a course of operative surgery on the dead body, (3) a course of bacteriology, (4) a course of ophthalmic surgery, and (5) a practical course of skiagraphy. The fee for this course, 33 guineas, is a severe tax.

Ought it not rather to be required that the naval surgeon should put in a three or six months' course quite free of all expense at least once in every six years, or preferably once in every three years—i.e., at the end of each commission? Should he not also be encouraged to take higher qualifications? A course of six months' study of State medicine would be of the greatest value in the service, and a surgeon who was willing to qualify and take the diploma in Public Health should, I think, be considered eligible for special promotion quite as much as a surgeon who has been fortunate enough to hold the post of house surgeon. As matters stand at present as warden of a medical college I am obliged to advise candidates for the Naval Medical Service to enter the service as early as possible and without seeking to hold house appointments, but if the suggestions I have made were adopted the candidates could enter just as early and prove far more valuable men in the end

I am, Sirs, yours faithfully,
MUNRO SCOTT,
April 30th 1902. Warden of the London Hospital Medical College.

SMALL-POX ON THE RIVIERA.

(FROM OUR SPECIAL SANITARY COMMISSIONER)

A Bad Season.—The Efficacy of Revaccination at Nice —Small-pox and the British and American Colony

THE Riviera winter season which has just concluded has proved disastrous in some places and nowhere is it qualified as a good season, although, as usual, the Principality of Monaco is the last to be affected by any evil circumstances that may arise. Indeed, the hotels, in spite of their numbers, have been well filled, and early in March, when I arrived at Monaco, it was with some difficulty that I could secure a suitable room. Now, of course, the great bulk of visitors have left and this is the moment when all concerned have time to pause and to consider the situation.

There are two principal causes that have produced the unfavourable result—namely, small-pox and the war No explanation is necessary to show that the war has compelled many British families and tourists to postpone the pleasure and the expense of wintering in the south. This is an unhappy circumstance over which local enterprise and the municipalities of the Riviera resorts had no control. The same cannot be said with regard to the prevalence of small-pox. Ever since British visitors have frequented the Riviera and English papers have published descriptions of the various attractions of this favoured coast, protests have been uttered against the want of proper sanitation and efficient drainage As a consequence there have been various improvements effected, but more remains to be done than has actually been achieved. In one respect especially there has been the most reprehensible neglect and that is in regard to the provision of isolation hospitals for infectious cases This great grievance was rendered distressingly obvious during this winter's season by the prevalence of small-pox. Nothing can be more alarming and painful than the position of a person away from home and country and stricken down by small-pox while staying in an hotel. In England a stranger would be removed in a proper ambulance by well-trained attendants to the fever or small-pox hospital where he would find the best sanitary conditions, medical attendance, and highly trained nurses. The room in his hotel would be thoroughly disinfected and the risk incurred by the other inhabitants of the hotel would be reduced to a minimum If, on the Riviera, the authorities insist on removing the patient they can only take him to the general hospital where he will be nursed by untrained sisters who know more about proselytising than about *nursing and he will be a source of* danger to the other patients. If he is allowed to remain in the hotel he endangers his fellow residents and is not in suitable surroundings for efficient treatment.

In such circumstances it is not surprising that the fear of small-pox has kept many intending visitors away from the Riviera. That it should have this effect is so obvious that the authorities concerned have done their best to conceal the fact that small-pox cases have occurred in several of the winter resorts But the policy of concealment always defeats its own ends. Absolute concealment is impossible and the absence of official information naturally gives rise to exaggerated rumours. Thus, we find in the *New Free Press* of Vienna a statement that there were during the season from 400 to 500 deaths from small-pox at Nice. This is undoubtedly an exaggeration. A few cases of small-pox occurred at Nice during the month of November, but it was not till Dec. 14th that several cases were notified on one and the same day, and the disease may then be said to have assumed an epidemic aspect. The disease was exceptionally virulent · the proportion of mortality was equal to about 32 per cent. of the cases. But this outbreak has in any case served one good purpose, for it has once more demonstrated the efficacy of vaccination. It may also be claimed that it has not been unconnected with economic and insanitary conditions Dr Balestre, director of the Bureau d'Hygiène of Nice, informs me that the inhabitants of the old town suffered most. He visited the two worst streets and the poverty, overcrowding, and filth prevailing there were beyond all description. The tall houses in those narrow, winding, steep, and picturesque streets have simply no sanitary accommodation at all In the streets there are some gratuitous latrines but there are no closets in the houses The inhabitants, for the most part very poor Italian labourers, empty out all their household refuse and soil into the streets. As there are no compulsory means of enforcing vaccination it is easy to understand how quickly small-pox may spread in such localities. On the other hand, where it has been possible to enforce vaccination, its beneficent effect, even in the presence of bad sanitation, has been most conclusively demonstrated. To make matters worse the inhabitants did all they could to conceal the cases which occurred among them and the presence of small-pox was often only known after a death had occurred. These poor Italians object to see a medical man and are still more opposed to the prospect of being removed to the hospital. But the soldiers belonging to the garrison of Nice often associate with these poor people and frequent the localities where they live. Every soldier is vaccinated; and, if there is no result, he is again vaccinated three times consecutively and then only is he judged to be immune. The garrison at Nice this winter amounted to about 3800 soldiers and there has not been one single case of small-pox among them. If, however, are added to the garrison all those who are employed by the public municipal or departmental administrations, the State tobacco manufactory, and the railway and tramway companies, we find a grand total of about 10,000 persons who have now all been revaccinated. Among these 10,000 people there were 14 cases of small-pox previously to vaccination and two other persons who had avoided being revaccinated had small-pox.

With respect to the well-to-do classes and the visitors to Nice there has been the same immunity from small-pox among those who had been revaccinated. But it would be a mistake, according to Dr. Balestre's opinion, to consider such immunity as absolute. To his personal knowledge there have been a few cases among people who were successfully revaccinated. On the other hand, though this has been a most virulent epidemic such cases among the revaccinated were of the mildest type and the patients all promptly recovered. Among his private patients Dr. Balestre noticed that in well-to-do families small-pox attacked the one member who had not been revaccinated while it spared all the others. Dr. Balestre is tempted to believe that the force of infection varies according to the virulence of the disease and that vaccination is not so efficacious when the disease prevalent is of the worst type. This may explain why a few persons who were revaccinated nevertheless contracted small-pox. It is true that they only suffered slightly but had the disease prevalent been of a milder character it is probable that they would not have suffered at all. Whatever may be the value of this conjecture, Dr. Balestre, as chief of the Bureau d'Hygiène, has had the best opportunity of judging and therefore I need make no apology for giving his opinion.

I can only find record of six cases of small-pox occurring among the members of the British and American colony at Nice. Some of these cases were, however, very characteristic. Thus in one large household the servants and others were revaccinated with the exception of two brothers. Shortly afterwards one of these brothers contracted small-pox; the other hastened to be vaccinated. Together with all the other members of the household he has escaped from the infection. Another and a particularly dramatic case relates to a lady who was a Christian Scientist. As such she was much opposed to vaccination and had persuaded a young gentleman not to be vaccinated. Hearing of this a lady remarked to her that she hoped that no evil would result from her action. Within a week of this warning the Christian Scientist died from small-pox. The young gentleman, her convert, thereupon once more changed his opinion and is now to be congratulated on having been successfully vaccinated. The third case was that of an old gentleman who lived so isolated a life in his villa, only going out in his own carriage, that he thought he was quite safe. He would have been better protected by vaccination, for he contracted small-pox in spite of his isolation. Altogether, of the six British and American visitors who contracted small-pox two died and none of them had been revaccinated.

One more incident may be mentioned as illustrating the efficacy of revaccination. There is at Nice an almshouse which contains 350 inmates. They were all revaccinated except half a dozen bedridden and aged persons. None of the latter were under 70 years of age and it was not thought necessary that they should be revaccinated. Nevertheless, one of these patients—he was 80 years old—contracted small-pox. This was the only case that occurred among the 350 occupants of the almshouse In face of this experience age is no longer accepted as an excuse and many very aged persons have now been successfully revaccinated.

Undoubtedly of the winter resorts Nice has suffered most from the present visitation of small-pox but there have been cases in nearly all the other towns and even in one of the very best hotels at Monte Carlo. With proper methods and facilities for isolation such occurrences need not have caused alarm. It is not as if small-pox had prevailed only on the Riviera. The reverse is the case, and the Riviera has only suffered from the reflex influence of what is occurring in many other parts of Europe. But until a proper isolation service is organised throughout the Riviera the health resorts will continue to suffer from what are sometimes unjustifiable panics and often exaggerated alarms.

Nice, April 26th.

THE GERMAN SURGICAL CONGRESS.

(FROM OUR BERLIN CORRESPONDENT.)

THE thirty-first Congress of the German Surgical Association met in Berlin on April 2nd, Professor **KOCHER** (Berne, Switzerland) being in the chair. The great hall of Langenbeck House was overcrowded, the number of the members having increased from 130 in 1872 to nearly 1300 in 1902, of whom 659 were present, so that many had to find accommodation in the galleries. A remarkable fact was the relatively large proportion of foreign members, especially Dutch, Scandinavian, and Russian. France was represented by Dr. Doyen who spoke several times during the congress, and Great Britain was represented by Mr. W. Arbuthnot Lane. Professor Kocher in his inaugural address mentioned the members of the association who had died during last year, making especial reference to Staff Surgeon-General Dr. von Coler, to Professor Julius Wolff, well known as an orthopædist, to Dr. Schuchardt, to Dr. Langenbuch, and to Sir William Mac Cormac. The association then unanimously agreed to the election as honorary members of the following gentlemen, whose names were proposed by the committee: Professor von Bergmann and Professor König of Berlin, Professor Guyon of Paris, Professor William Macewen of Glasgow, Professor Keen of Philadelphia, and Professor Durante of Rome.

Military Surgery.

The first meeting was devoted to a discussion on the dressing of wounds on the battle-field, especially in the light of the experience gained during the present war in South Africa.

Professor **VON BRUNS** (Tübingen) said that from a bacteriological point of view a bullet-wound must be regarded as infected, for bacteria were present everywhere During the early years of the antiseptic era military surgeons in the Turco-Russian war tried to apply the principle of Lister's method even on the battle-field by carrying out thorough disinfection, drainage, &c. It was the merit of Professor von Bergmann, then in the service of Russia, to have shown that this was practically a failure and that uncomplicated gunshot wounds had a marked tendency to run an aseptic course if they were only covered with an antiseptic dressing to the exclusion of any other procedure. This was still more the case at the present time when the small-calibre bullet produced wounds with a very small aperture of entrance. These principles were also followed in the South African war, the wounds being merely covered with a dressing, and this being done on the British side as early as possible and previously to the removal of the patient from the place where he fell. Professor von Bruns insisted especially on the importance of the latter precaution, as the removal of a wounded man even for a short distance without an adequate dressing was likely to have the worst possible consequences. The early dressing of the wounded on the place where they were found during a battle was a great advantage to them and was, of course, very dangerous to the military surgeon, who had to work sometimes under the fire of the enemy. Professor von Bruns stated that the members of the Royal Army Medical Corps were often to be seen attending to the wounded in positions exposed to the fire of the Boers. Alluding to Count Bülow's words in the German Parliament he said that the Royal Army Medical Corps had thus proved, like the other corps of the army, that its members knew how to die. Under an early and simple dressing the wounds dried up and healed without suppuration A crust was formed when a powder like dermatol or xeroform was put on the wound, but impermeable material, such as caoutchouc tissue, protective silk, and the like, were to be avoided because they hindered the wounds from drying Instead of the powder a dermatol paste might also be used, but bandages were sometimes rather difficult to apply on the battlefield and might be replaced by caoutchouc plaster Fractures of bones must be immobilised previously to the removal of the wounded man It was not only the first dressing but also the first removal which, according to the late Professor Volkmann, decided the man's fate.

In the discussion Dr. BERTELSMANN (Hamburg), who had served with the Boers at the siege of Mafeking, said that he had seen 52 wounds heal without suppuration. This took place although the hygienic conditions in the Boer camps were far from being satisfactory and the transport and other arrangements were quite unsuitable for their purpose In his opinion the good results were obtained because the wounds were scarcely touched by the finger or by an instrument, he only applied some gauze and fixed it by adhesive plaster. Perhaps it was due to the dryness of the South African atmosphere that the wounds healed well under a crust of dried blood.

Professor KÜTTNER (Tübingen), who had been with the German Red Cross Ambulance in the South African war, as well as in the Turco Greek war and in the China expedition, was of opinion that climatic conditions had but little influence on wounds, as he had obtained the same results in countries far removed from one another, provided that the aseptic and conservative method was used and the wounds were touched as little as possible. In this way the wounds produced by the modern rifle when uncomplicated healed very well and much better than did those inflicted by the bullets of the large-bore rifles formerly used. Of all his bullet wounds only 12 per cent. suppurated and of the shell wounds 40 per cent.

Dr HILDEBRANDT, one of he medical officers of the German Red Cross Ambulance with the Boers, spoke on the treatment of abdominal wounds There was at present a marked tendency to abstain from laparotomy in these cases because they were believed to have the best chance of recovery when they were left alone, but this was in Dr Hildebrandt's opinion erroneous, for the mortality was still at the rate of 70 per cent. Men who after two or three days had come to the field hospitals without complications generally recovered without operation, but when perforation of the intestines had led to peritonitis operation at that stage was nearly always unavailing If, therefore, perforation of the intestines were known to exist laparotomy and suture of the intestine might be performed at once, even at the dressing station of the field ambulance at the front; notwithstanding the contrary opinion of other military surgeons, and especially of the late Sir William Mac Cormac, he thought that these operations were justifiable.

Professor TRENDELENBURG (Leipsic) showed a patient whose heart had been entered by a bullet and who had been conveyed to the hospital in a state of severe shock but without hæmorrhage into the pericardial or pleural cavity It was a striking spectacle when by means of the Roentgen rays the bullet was seen moving freely within the ventricle; at present the bullet was adherent to the cardiac walls and only moved in unison with the cardiac movements. The patient was now in good health and he complained of nothing

Treatment of Fractures

Dr. NÖLKER (Heidelberg) recommended the suture of the fragments in certain cases, namely, in compound fractures, in fractures of both bones of the same limb—for instance, the tibia and fibula—and in fractures where the displacement of the fragments rendered exact apposition impossible. The dangers of suture after the injury were not very great, especially when only one bone was broken, in bones covered by thick layers of soft tissue, such as the femur, or in the neighbourhood of joints, the operation was more complicated and therefore not without risks. Sutured bones healed somewhat slowly because the development of callus was not assisted as in other cases by the mutual friction of the fragments.

Mr ARBUTHNOT LANE gave an account of about 150 fractures in which the fragments had been sutured by him. He recommended the use of silver wire.

An animated discussion took place with respect to the methods to be followed, the time of operation, and the material to be used Some surgeons recommended that the fragments should be secured with nails or screws

Professor SCHEDE (Hamburg) used ivory pegs which were left in the wound

Professor SCHLANGE (Hanover) uttered a warning against operating without proper indications In the majority of cases fractures did not require operation but united under treatment by extension and fixation, which must continue to be the normal procedure. Suture was, however, sometimes indispensable, as in the so-called spiral fractures, in fractures of the tibia, and in fractures in the neighbourhood of the joints Professor Schlange had obtained good results with aluminium-bronze wire.

(*To be continued.*)

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

An Epidemic of Dengue Fever in Rangoon.—A Petition from the Bombay Medical Union.—The Plague Epidemic

IT is reported that after an absence of about 30 years dengue fever has appeared in Rangoon and has spread rapidly The disease is very contagious, several cases occurring in the same house. It is said to have been prevalent of late in Penang and Singapore, so that it has probably been brought from the Straits

The Bombay Medical Union has submitted a petition to the Viceroy in which it is urged that whereas the Government has in the past refused to appoint Indian medical men to the public service unless they had passed a special competitive test, several medical officers brought out for plague duty have now been posted to the Indian Medical Service without competitive examination; the Bombay Medical Union prays that Government will consider the claims of graduates of Indian universities and of other natives to appointments in the Indian Medical Service and will also increase the number of civil surgeoncies allotted to civil assistant surgeons This is the old question of admitting native medical men without going through the prescribed competitive examination in England. After all, very few of the European plague officers have accepted the commissions offered so that the commissions must be looked upon more as rewards for services rendered rather than as any intention of altering the conditions upon which medical men can enter the service It is generally acknowledged in the service that it would be very undesirable to relax the conditions now existing except in very special circumstances.

The last returns of plague deaths in India show that the disease is still spreading There were 26,108 deaths in the week ending March 22nd, as against 25,655 for the previous seven days. The Punjab shows the chief increase—16,829 deaths having been there recorded. In the Bombay Presidency as well as in the Bengal Presidency there was a decline and so also in the Madras Presidency There were more deaths (932) in Kashmir and also in Karachi city (74) Returns issued later show that the diminution in Calcutta (420) was only temporary—the last week showing a rise again to 550 deaths. Notwithstanding the special precautions to keep plague out of Simla the disease is approaching closer and closer and it will probably be only a short time before the native quarters become invaded. In Bombay city the advance of the outbreak has apparently made a halt as the deaths recorded from plague were only eight more than in the preceding week. The general mortality of this city is very high, the total deaths for the week ending March 27th being 1676, with a rate of 112 30 per mille. As there is very little cholera or small pox or other epidemic disease in Bombay the high mortality suggests that there must be more plague deaths than are accounted for This, however, has been the statistical history since the plague first appeared in 1896.

April 3rd

The Plague Epidemic.—Medical Reform Before the Universities Commission

The high plague mortality throughout India continues. This week there have been registered 23,226 deaths, as against 23,836 during the previous seven days There has been an increase in Bombay city (957 against 816), in Karachi (128 against 70), in Calcutta (689 against 550), and in Kashmir (262 against 216); but a decline in the Madras Presidency (93 against 125), in Bengal (1256 against 1777), and in the Punjab (14,871 against 16,675). The great development in the last province has probably reached its height and the outbreak will now decline. The mortality in Bombay city is still on the up grade, as 1902 deaths—a rate of 127·45—were recorded for the week ending April 2nd. As the plague mortality is returned at 999 this leaves 903 deaths to be accounted for. These figures are about 300 in excess of the normal. Calcutta city has more than double its usual mortality but the excess is accounted for by the Plague Department, and except for plague the mortality would not be excessive. Almost every week we read of extension of the disease to fresh districts. It is now spreading among the Hill States.

The subject of medical reform in India has been brought before the Universities Commission now sitting in Calcutta. It is complained that the medical chairs are filled solely by members of the Indian Medical Service and that consequently the field of choice is contracted. As a consequence the teachers are not always the best available and the college professors who act as consultants for their respective Presidencies are not always highly proficient. Further, the change of professors, or the change of subjects which one professor has successively to take up, prevents the proper study of any one subject. It is suggested, therefore, that these chairs should be thrown open as is done in Great Britain. It was also complained that there was so little incentive for original research and it was suggested that regular medical research ought to be a part of the work of the university.

During the absence on six months leave of Mr. J. Nield Cook the duties of medical officer of Calcutta will be carried on by Dr. T. Frederick Pearse who has acted previously in the same capacity.

April 10th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Lying-in Charity.

THE Birmingham Lying-in Charity dates far back into the pre-antiseptic era. Some 40 years ago, owing to the mortality among the in-patients, the building used as the hospital was given up and the work of the charity was limited to the attendance upon patients in their own homes. The annual report, which was read before a meeting of the governors on April 15th, showed that during the past year 925 cases had been attended without the death of a mother and the charity was stated to be doing a valuable work unobtrusively and economically. The report of the Medical Committee drew attention to the necessity of important changes being made in the administration of the charity. It pointed out that the time has come for the extension of the area of usefulness of the charity and it emphasised the desirability of providing a central home in which not only serious cases, or those requiring operative treatment, could be admitted but where also nurses could be trained under suitable superintendence and effective teaching could be given in the knowledge and practice of midwifery. The report was favourably received and adopted; it is hoped, therefore, that extensive additions will be made in this valuable department of the charity.

The Small-pox Epidemic.

The public mind is far from easy upon the question of the spread of small-pox in our midst. At present there does not appear to be sufficient ground for apprehension on account of the number of cases arising. The Health Committee is actively isolating suspected and infected patients. At this time there are 10 cases in the isolation hospital and every precaution is taken to obtain early notification and removal. Individual cases occurring in neighbouring towns add to the fear that the epidemic may be insidiously spreading, patients—generally of the tramp class—having been located at Walsall and Tamworth. Meanwhile the effect is to induce a large number of people to be revaccinated as a safeguard against infection.

The Spread of Diphtheria.

An association known as the Birmingham Sanitary Council appointed a deputation which waited upon the Health Committee of the Town Council on April 23rd to set forth its views upon this subject. It was pointed out that Birmingham does not provide special isolation wards for diphtheria patients or for patients in whom that disease is complicating others and that many large towns were already in possession of suitable accommodation for such cases The chairman of the Health Committee promised that the question should receive consideration, but he stated that the committee had its hands full at present and that the tax upon its hospital accommodation was very severe. It should be borne in mind that although there are no diphtheria wards the Health Committee is doing what it can in other directions to check the spread of the disease. For instance, an arrangement has been made with the bacteriological department of the University to conduct examinations of the sputa of patients supposed to be suffering from this disease as a means of diagnosis. Recently also similar arrangements have been concluded for re-examination so as to give an assurance of recovery and freedom from the disease. So well has this been carried out that at many of the principal schools a pupil after suffering from diphtheria is not allowed to return until a certificate is produced stating that a bacteriological examination shows that he is absolutely free from the disease.

The First Horse Ambulance.

The first horse ambulance ordered by the corporation for the use of the city arrived on April 18th. Internally the fittings consist of two removeable stretchers supported one above the other. There is a space for an attendant and the lower stretcher has an adjustment for raising or lowering one end in order that the injured person may have the minimum of discomfort when the vehicle is ascending or descending a hill. A supply of splints for fractures is provided in racks at the sides and the usual surgical dressings are contained in boxes placed in the front of the van. As compared with present appliances this is a great improvement. No doubt others will be placed in various positions in the city, thus providing a very efficient aid to meet emergencies.

April 29th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Delamere Sanatorium: Annual Report of the Consumption Hospital.

THE number of applications for admission to the Delamere Sanatorium, which is in connexion with the Consumption Hospital, during the past year far exceeded the accommodation and the committee had to refuse admission to many applicants who would probably have benefited by treatment at the sanatorium. The actual cost of building and furnishing the sanatorium was £15,295. In addition to the main building four bungalows to accommodate 16 patients were erected and furnished, as well as shelters and seats in different parts of the grounds. £2800 were received during the year as special donations to the sanatorium. Now that the sanatorium was in full working order the committee was considering the re-construction of the Mount Pleasant Hospital in accordance with the resolution adopted at the annual meeting on March 27th, 1899. The number of in-door patients treated at the Consumption Hospital on Mount Pleasant during the year was 218. In the out-door department there were 1984, whilst the total number of attendances reached 16,291. Out of 47 cases treated at the sanatorium there had been only one death, whilst 74 per cent. of the cases had been cured and 20 per cent. showed no improvement. Mr. Charles Threlfall had subscribed £1000 for the endowment of a bed at the sanatorium. Sir William Tate had also given £500 for the same purpose, together with an annual subscription of £21.

New Appointment for Major Ronald Ross, F.R.S., late I.M.S.

Major Ronald Ross, the Walter Myers lecturer at the Liverpool School of Tropical Medicine, has accepted an appointment at the Jenner Institute of Preventive Medicine in London. Major Ross's departure from Liverpool will be regretted much by his numerous friends. His name always will be associated with the expeditions despatched to the West Coast of Africa by the Liverpool School of Tropical Medicine in connexion with the investigation of malaria and the mosquito theory.

The Proposed Liverpool University.

On April 25th the finance committee of the city council passed a resolution recommending the council to present a petition to the King in council praying for the granting of a charter for the foundation of a university for Liverpool £157,000 have been already subscribed towards the £330,000 required for endowments in aid of the proposed university

The New Local Fellows of the Royal College of Physicians of London

Dr James Barr, honorary physician to the Liverpool Royal Infirmary, and Dr A. F S Grünbaum have been elected Fellows of the Royal College of Physicians of London.

Donations to Local Charities

By the terms of the will of the late Mr James Barrow of Waterloo the Liverpool Royal Infirmary and the David Lewis Northern Hospital each receive £500 , and the Royal Southern Hospital, the Stanley Hospital, the Bootle Borough Hospital, the Children's Infirmary, and the convalescent home at Woolton, each receive £250 —The honorary treasurer of the Bootle Borough Hospital has received from the trustees of the late Miss Olivia Atherton a cheque for £500 for the endowment fund of the hospital The Liverpool Country Hospital for the Chronic Diseases of Children also receives £1000 by the will of the late Miss Olivia Atherton.

April 29th

NORTHERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENT)

University of Durham.

A CONVOCATION of the University of Durham was held on April 26th in the Library of the College of Medicine, Newcastle upon Tyne The Warden of the University, Dean Kitchin, presided. The principal matter of interest in the proceedings to medical men was the conferring of the degree of Doctor of Civil Law upon Sir William Selby Church, Bart., President of the Royal College of Physicians of London, and upon Professor Thomas Annandale Regius Professor of Clinical Surgery in the University of Edinburgh

Annual Report of the Newcastle upon Tyne Royal Infirmary

The 151st report of the Newcastle Royal Infirmary has just been published and it shows that the amount of work done by this excellent institution continues to increase. The number of patients admitted during the year was 4559, being an increase of 301 on the number for the previous year while the number of out-patients and casuals amounted to 43,381, making 47,940 in all. The total ordinary income for the year amounted to £13,544 4*s* 9*d* , which included no less a sum than £5530 11*s* 7*d*. subscribed by the working men, while the expenditure for the year was £17,505 4*s* 3*d*. 3258 operations were performed during the year , of those, 111 were for appendicitis with 17 deaths and 184 were for the radical cure of hernia with only two deaths. The report says 'It is with a profound feeling of satisfaction that the committee report that at last the work of building the new infirmary has commenced," but the feeling of public satisfaction will be even more profound when they have to report that the work of building has been completed

Death of Charles P G Crichton, M.B , B Ch. Glasg , of Chester le Street.

The death took place on April 28th, at Chester le-Street, Durham, of Dr Crichton, one of the assistants of Dr W H. Renton. The deceased, who was not quite 30 years of age, took a chill about a week ago which developed into pneumonia, to which he succumbed He came from Glasgow and he showed such skill and tact in his profession that in the few months he was at Chester le-Street he gathered round him a considerable circle of friends. He was known and respected as one of the hardest workers among professional men in the district The deceased was unmarried

Health of South Shields

Dr J J Boyd, medical officer of health of South Shields in his annual report for 1901 points out that the high birth rate which has characterised the borough for many years is still maintained. Last year it was 36 8 per 1000, as compared with 28·5 for England and Wales. The death rate was rather high, being 20·6 per 1000 as compared with 16·9 for England and Wales. Infantile mortality was heavy , out of every 1000 children born 169 died before reaching the age of one year This was mainly due to an epidemic of infantile diarrhœa. Dealing with zymotic diseases Dr Boyd points out that there were no cases of small pox in South Shields during last year, although several have occurred since Scarlet fever, however, prevailed in epidemic form, 1283 cases being notified and 59 deaths being registered. Tuberculosis was responsible for 231 deaths Not much so far has been done with a view to diminish the ravages of this disease, although a beginning has been made. Whenever a death from phthisis now occurs a letter is sent to the occupier of the premises, *pointing out the infectious character of the disease* and that the infection becomes attached to all articles used by the patient and to the rooms in which he has been living and the importance of thorough disinfection. The corporation, it is explained will supply suitable disinfectants, and will send for all carpets, hangings, &c., which will be disinfected by the corporation disinfector The next step, Dr Boyd says, would be to adopt some system of notification of cases and to take some practical action against the habit of indiscriminate spitting

Newcastle-on Tyne April 29th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Cardiff Refuse Destructors

ALTHOUGH Cardiff has been foremost among South Wales towns in other sanitary improvements it has been strangely laggard in the matter of the disposal of refuse. In the adjoining town of Barry a refuse destructor has been installed nearly two years and even in the Rhondda Valley there has been one at work for nearly a year This latter differs materially from the ordinary form of destructor and is known as Mason's gasifier It is provided with an iron chimney only 40 feet high and there are absolutely no offensive fumes given off. For more than six years members of the Cardiff Corporation have been examining and reporting upon destructors of various types in other towns and a recommendation has now been made to erect two destructors of eight cells each capable of dealing with 1200 tons of refuse weekly at an estimated cost of £61,500 At the present time there are 1800 tons collected in the town each week and *this is all deposited in various* tips on the outskirts of the borough. The types of destructor recommended for erection are those of Messrs. Meldrums and of Messrs Hughes and Sterling

Pauperism in Cardiff

At the meeting of the Cardiff Board of Guardians, held on April 26th the Poor law inspector of the Local Government Board (Mr F T Bircham) gave some interesting comparative statistics with reference to the extent and cost of pauperism in the Cardiff Union. During the past 10 years he said that the population of England and Wales has increased 12 per cent. and the number of paupers 8 per cent., but the rate of pauperism has decreased 19 per cent. while there has been an increase in expenditure of 22 per cent. In the Cardiff Union during the same period the population has increased 31 per cent., the number of paupers 54 per cent. and in the rate of pauperism there has been an increase *of 10 per cent., with an increased* expenditure of 54 per cent. This increase in the expenditure is due to more adequate remuneration to the officers, to increased accommodation for the inmates, and to improvements in the nursing arrangements, as well as to increased amounts given in outdoor relief Mr Bircham emphasised the importance of paying very particular attention to every application for outdoor relief, for which purpose alone the Cardiff Board of Guardians distributes £400 weekly

Small-pox

There has been a recrudescence of the epidemic of small pox in Swansea where there are now in the hospital 10 cases of the disease Hitherto the patients have come from a restricted area but the last was from a more remote district. At Aberdare there is one case of small pox and this patient has infected a collier in the Rhondda Valley There has only been one case of small pox in the latter district during the past 10 years. *In the Pontypridd Union*, which includes the Rhondda, there are very few unvaccinated children but only a small percentage of the inhabitants are protected by revaccination.

Housing of the Poor in Bristol

In 1891 the average number of persons per house in Bristol was six and although in 1901 this average was found to be only 5·6 it is probable that the reduction was due more to the extension of the city boundaries than to any very marked improvement in the crowded parts of the town. Although there are in Bristol no very large unhealthy areas there are still many courts and insanitary dwellings which must prejudicially affect the health of the inhabitants and it is to these that the Committee for Promoting the Better Housing of the Poor turns its attention. The annual meeting of the committee was held on April 25th when the President, Mr. Lewis Fry, commented favourably upon the work accomplished during the past year. Mr. Fry deprecated the adoption by municipal authorities of extensive housing schemes as likely to stifle private enterprise and he advocated greater facilities for taking working men rapidly to and from their work. It appears that many of the insanitary dwellings which the committee desire to see abolished are built in groups of four or eight upon land which was formerly the garden of a house facing the street and accessible only through the street-door of that house. As the surrounding property is often very valuable it is almost impossible to clear an area and the houses can only be dealt with effectually piecemeal.

Death of Alfred Richards Smith, M.D., L.R.C.S. Edin.

Through the death on April 20th of Dr. A. R. Smith the medical profession in Hereford has lost one of its oldest and most valued members. Dr. Smith was born in Hereford in the year 1833 and received his early education at the Cathedral School, afterwards proceeding to Edinburgh University, where in 1858 he obtained the gold medal in anatomy and took the M.D. degree in 1861, being admitted a Licentiate of the Royal College of Surgeons of Edinburgh in the same year. Shortly after qualifying he began practice in Hereford and in 1872 was elected on the staff of the Herefordshire Infirmary. At the time of his death he was consulting physician to that institution and held a similar position in connexion with the Herefordshire Dispensary. During the past few years he had gradually dropped out of practice except in the capacity of consultant. Although of a retiring disposition and by no means self-assertive there is no doubt that the high character of Dr. Smith and his strict observance of the dictates of medical etiquette have left their mark upon professional life in Hereford. He was a musician of considerable ability and frequently acted as organist at one of the city churches. He leaves a widow and one daughter.

A Warning to "Conscientious Objectors" to Vaccination.

At the Cheltenham police-court on April 17th three defaulters were summoned under the Vaccination Act. Evidence showed that they had previously satisfied the magistrates of their conscientious objection to vaccination but had refused to pay the fee of 1*s.* 6*d.* due for each certificate, and consequently did not receive the certificates within the required seven days. For the defence it was contended that the defendants had acted under a *bonâ-fide* misapprehension of the magistrates' power to order the payment of this fee and they asked the bench to exercise their discretion and now grant the exemption. To this course the magistrates assented, though intimating that the action must not be taken as a precedent now that the law was established.

Queen Victoria Jubilee Convalescent Home, Bristol.

The second annual report of this institution which has just been issued shows that 1015 patients were admitted during 1901; of these, 12 were returned to their homes as unsuitable cases, 35 were discharged unimproved, and the remaining 968 derived considerable benefit from their stay at the home. The financial statement was satisfactory and showed that the total expenditure for the year amounted to £2299 and that a favourable balance of £39 remained.

April 28th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Prevention of Consumption in Ulster.

AN interesting letter from the honorary secretary of the Ulster Branch of the National Association for the Prevention of Consumption appeared in the *Irish Times* of April 29th, in which it was shown that although the mortality from consumption in Ulster and Leinster is higher than that in any other districts in the United Kingdom—the death-rate being three times as high as in high parts of England—no steps have been taken to lessen the prevalence of the disease. The letter describes the measures adopted for this purpose on the Continent, in the United States, and in many English towns, such as Liverpool and Manchester, and contrasts the scientific precautions which have succeeded in New York in lowering the death-rate from consumption during the last five years by 35 per cent. with the deplorable apathy in this regard which still prevails in Ulster.

The Case of Small-pox in Belfast.

The Belfast Poor-law Guardians having protested in reference to a man with small-pox being sent from the jail (in which there was a good infirmary), where there were 500 inhabitants, to the workhouse, where there were 3500 inmates, the Secretary of the Local Government Board has replied enclosing a letter from the General Prisons Board, Dublin Castle, to the effect that the prisoner's release from prison took place on March 13th, and that as he was then suffering from small-pox it would obviously have been improper to allow him to return home. It turns out that this is hardly a full and accurate statement, as the man was arrested in Glasgow on Feb. 26th on a charge of bigamy, and conveyed to Belfast, arriving there on the morning of the 28th. On that date he was brought before the court and remanded to jail until March 6th, when he was again remanded for a week. On the 13th he was unable to attend the court and on that day he was ordered by the Lord Lieutenant to be removed from Belfast Jail to hospital, as he was suffering from small-pox. The guardians have decided to let the Local Government Board know the real facts of the case and they will decline in future to receive such a case, there being ample accommodation, in their opinion, in the jail infirmary, or the patient can be sent to the wooden isolation huts to be provided by the Public Health Committee of the Corporation at their new fever hospital at Purdysburn, near Belfast.

The Mater Infirmorum Hospital, Belfast.

From the financial statement of this hospital for the year ended Oct. 31st, 1901, it appears that a sum of £4000 has been received from various sources for defraying current expenses and the excess of expenditure over income for the year amounts only to £300, a small deficit indicating the great care exercised in the disbursement of the funds. The last Saturday in May is fixed as the day for the hospital collection in aid of the funds of the Mater Infirmorum Hospital.

Milk Prosecutions.

The adjourned cases of prosecution of Belfast dairymen for having sold milk deficient in fat were before the police-court on April 21st. The city analyst had certified that there was a deficiency of 13·3 per cent. of normal fats; but after hearing the evidence, the resident magistrate dismissed the prosecution on the ground that there was no evidence that there had been any abstraction of fats, the evidence being that the milk was sold just as it had come from the cows. By an order of the Agriculture and Technical Education Department for Ireland, dated August 2nd, 1901, it is provided that where a sample of milk is found deficient in fats there is left upon the dairymen the onus of proving that the milk is genuine. The importance of this magisterial decision is that it is in antagonism to the theory that a standard can be set upon which to judge whether milk is or is not genuine. The evidence showed that the amount of fats and solids which milk contains may vary according to the weather, there being less fat and more solids in cold severe weather than in mild warm weather. In cold weather more fat is consumed to maintain animal heat than in warm weather and so there is less fat in the milk. The milk standard, it would therefore seem, ought to vary according to the state of the thermometer and in a variable climate like Ireland it is difficult to imagine the thermometer setting a standard to anything. In any further prosecutions evidence as to the chemical composition of the milk will be of little avail.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Radium as a Means of Sight for the Blind.

AT the meeting of the Academy of Medicine held on April 15th M. Javal showed the meeting that radium, the metal discovered by M. Curie, possesses the singular quality of continuously emitting rays of a kind similar to kathodal rays or the rays of Roentgen. M. Giesel has found out that compounds of radium produce a perception of light in the eye even when a screen is interposed between the eye and the radium compound The screen may be of metal and the whole of the visual field appears full of light. The same sensation of light is felt if a glass tube containing a few centigrammes of radium chloride be pressed against the temple. M. Javal and M. Curie have made some experiments with radium in blind persons. If the retina be healthy they experience a sensation of light exactly comparable to that felt by a "sighted" person. In a patient who was completely blind owing to infantile purulent ophthalmia which had made the corneæ quite opaque the light emitted by the radium was distinctly seen. If, then, this patient could have his corneæ made transparent he would have good vision.

New Privileges of the Nursing Staff of the Hospitals

M. Mourier, the Director of the Assistance Publique, has given his adhesion to a proposition laid before the Municipal council by M. Ransom. The proposal is that there should be erected as soon as possible on land belonging to the Assistance Publique a sanatorium of 50 beds for the reception of such nurses, both male and female, who have become infected by tuberculosis during their attendance on the sick. M. Mourier, for his part, said that the Assistance would do everything in its power to carry out the scheme with a due regard both for the interests of the nurses and for the public interests of the Assistance. The Municipal Council has furthermore decided to set aside a small plot of land in the Eastern Cemetery for the interment of those nurses who may die from diseases contracted while nursing the sick. In this way the names of victims to professional duty will be kept in remembrance, as are those of firemen and other municipal workers.

Obituary.

Dr. le Rendu has just died at the age of 58 years from cancer of the stomach. He was a pupil of Potain and had been physician to the hospitals, an *agrégé* professor at the faculty of medicine, a member of the Academy of Medicine, and a Chevalier of the Legion of Honour. He leaves behind him a great reputation as a clinician and a practitioner of the highest honour He wrote several books on diseases of the heart and of the liver and since 1890 had been general secretary to the Hospitals Medical Society.—The death is announced of M. Filhol, professor of Comparative Anatomy at the Museum. He was 60 years of age and was formerly a professor in the provinces. In 1895 he succeeded to the chair of G. Pouchet at the Museum. He was a Member of the Academy of Medicine and of the Institute (the Academy of Sciences).

Dr. Doyen.

The widespread notice which was taken of the operation for separating Radica and Doodica has given rise to many attacks upon Dr. Doyen. These culminated when Dr. Legrain publicly asserted that Dr. Doyen had allowed kinematograph films of the operation in question to be exhibited in an acrobat's booth and an enormous poster announcing that this was the fact to be exhibited outside the booth. Dr. Doyen thereupon sent his seconds to Dr. Legrain. After the seconds of the two medical men had conferred it came out that Dr. Legrain had made a mistake. The poster actually was fixed to the booth but it was simply to draw the public. Inside there was no kinematograph show nor anything else coming from Dr Doyen. There were, however, two large wax figures supposed to be Radica and Doodica. Dr Legrain therefore wrote an apology to Dr. Doyen which has been published in the journals.

April 29th.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

Eyesight of School Children.

DR. ADOLF STEIGER, a well-known ophthalmologist, has just published a full account of the examinations of children's eyesight which he has made at the public schools of Zürich for the last eight years (1894 to 1901) His observations show a defective state of the eyesight in 19 1 per cent. of 19,947 children examined. The percentages of the different diseases of the eye were as follows: hypermetropia, 1·2; myopia, 0·9; astigmatism, 8·6; cramp of the muscle of accommodation, 1·4; strabismus and amblyopia, each 1; maculæ corneæ, 1·3; and various other defects, 1·5. In 2 per cent. of the cases examination was not possible owing to the behaviour of the children (fright, crying, &c.). Dr. Steiger found that an exact ophthalmometric examination of eyes with defective vision was an absolute necessity as it led directly to the discovery of the high percentage of astigmatism which was generally overlooked in the older statistics. The usual primary examination (with a rectilineal figure of the shape E turned in four different positions and not with letters) is now conducted by one of the official town physicians who have the superintendence over all the hygienic affairs of the town pending the appointment of a medical man (*Schularzt*) who is to devote his time exclusively to matters of school hygiene. It is most necessary that these examinations should be made by a medical man and not by the various schoolmasters. 25 per cent. of all the school-children had deficient vision or were doubtful cases and they were sent to Dr. Steiger for special examination one by one accompanied by one of the parents In this way Dr. Steiger was in a position to give the necessary instructions to the parents and then he sent an official report to the schoolmasters in order to enable them to treat the patients appropriately. He supplied detailed written instructions with regard to the special attention to be paid to each child, such as the distance of the child's seat from the window or from the black board, the use of spectacles, &c. This report has to be added by the schoolmaster or his successor to the official report on the non-attendance of individual children and in this way there is a certainty that the schoolmaster will always remember the instructions given. No doubt this will have practical results. Dr Steiger merely informs the parents of the defective state of their children's eyes, makes his diagnosis, gives his advice, and refers the patients to the ophthalmologist or the polyclinic of the university. I must mention that the children of rich and poor almost alike attend these schools which cannot be compared with the board schools in England as at least 90 per cent. of all the children of all classes attend these gratuitous State schools where the best of instruction can be obtained It may, in fact, be said that we are suffering from the effects of over-education rather than otherwise Examinations of the organs of hearing are also officially conducted by aural surgeons. Such observations not only have a scientific import but will no doubt prove useful to the schoolmasters and beneficial to the children

Preliminary Education of University Students.

Students in Switzerland have up to the present time been able to enter the universities after having been six years at a public school and having had six and a half years of college education; they are then about 19 years of age. Greek used to be obligatory but may be replaced by a modern language. German and French are absolutely necessary, but the student can choose a minimum of two other languages among Hebrew, Greek, English, and Italian. This system has so far proved very satisfactory, securing a proper classical education and yet having regard to the fact that the study of modern languages is more and more desirable every year. The Federal authorities, however, have suddenly proposed quite a new plan without consulting the proper authorities in exact opposition to the philological opinions obtained. They propose that the college education should be of two kinds or systems—the one strictly classical, with obligatory Greek and Latin, and the other merely "humanistic," in which these languages would be replaced by modern languages. The prospect of students without any knowledge of Latin and Greek being admitted to a university has caused no small stir in the medical profession, and an unofficial poll has been taken for the purpose of ascertaining the state of opinion on the subject, with the result that 1470 medical men in Switzerland answered the questions put to them, and the vast majority—namely, 1302—expressed the view that the present system of classical education is desirable. It is, therefore, to be hoped that these opinions will take the form of an official protest by our new Aerzte Kammer, a committee which is elected by all the medical societies in Switzerland and is empowered to confer with the Government on matters of import to the medical world.

Zürich, April 25th.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Plague in Egypt in Recent Times.

MANY readers of THE LANCET will remember that plague appeared in Alexandria in April, 1899, and lasted until October, causing 46 deaths out of a total of 96 cases. During that summer two patients who had travelled from Alexandria were discovered at Damanhour, a town one hour's distance by train from Alexandria, but with this exception the disease did not spread outside Alexandria. A second outbreak took place in 1900, when 150 cases occurred, divided between Alexandria where plague existed from April until November and Port Said where the disease began in in April and was stamped out by energetic means in July. There was in addition one case at Damietta which was obviously imported from Port Said. A third recurrence began in April, 1901, which has smouldered gently on in various places ever since. Now that the disease has existed in the country for 12 months it is interesting to recapitulate the various sanitary bulletins which have been accurately published every day by the Sanitary Department. It appears that 382 cases have occurred during the year out of the whole population of 10,000,000 persons. Of these 223 have died, 112 of them dying under treatment in the various Government infectious hospitals, while the remaining 111 have been found dead by the sanitary authorities in their homes. In Alexandria there have been 41 cases, including 24 among Europeans and 17 among natives. At Port Said 21 cases have occurred, comprising seven among Europeans and 14 among Egyptians. At Zagazig the numbers reached the maximum of 67 cases, of which only four were among Europeans. At Tantah there have been 42 cases, including two among Europeans, and at Mit Camr there have been 17 cases, of which three were among Europeans. It must be remembered that the Europeans attacked have invariably belonged to the poorest classes, who lead lives as unhealthy as do the natives and who work with the natives bare-footed, or almost bare-footed. It is also interesting to note that not a single one of the 111 deaths outside the hospital occurred among Europeans. In the following towns and villages not a single European has been attacked: at Kom el Nour in the Dakahlieh province there have been 23 cases, of which seven are still under treatment; at Ziftah seven cases; at Abusir also seven cases in the Gharbieh province; and at Benha in the Galioubieh province there have been 10 cases. Plague has attacked Upper Egypt this winter for the first time for nearly 60 years, for there have been five cases at Minieh and 22 at Deshneh (Keneh). Quite lately a small outbreak has been discovered at Korashieh, a little village to which the infection was carried in February from Tantah to some nomadic Bedouins grouped about the village. Some of their huts were destroyed at the time, but the original case was not recognised as plague, and therefore no special plague precautions were taken. This is an accident which may occur at any time in the outlying districts, though of course all the country doctors have been carefully warned to be on the look-out for the disease. The record for the past week tells something of the usual sanitary measures which have been taken in the places where the disease is present. 20,019 rooms have been disinfected, 8229 rooms have been whitewashed, 14 sacks of clothing have been disinfected, while 958 sacks of rubbish from the interiors of suspected houses have been destroyed. In addition to this quiet work which the sanitary authorities are carrying on every day about 600 rats are killed and burnt each week. The whole world seems to be getting used to hearing of plague in their midst, and there has been very little talk about it in Egypt, and absolutely no alarm among Europeans or natives.

The Cairo Season.

The tourists are hurrying away to Europe as fast as they can after a very successful and healthy season. About 8000 of them have visited Cairo since November, no less than 800 having come in one batch from New York in the *Celtic*. For the last two winters influenza has been almost absent from Egypt though there have been a few sporadic cases among the residents As regards typhoid fever I have only been able to hear of six cases among the visitors, one of which ended fatally. It is impossible to say where in these six cases the disease was contracted but it is believed that at least two of the patients caught it from drinking water on the steamers which brought them to Egypt. Modern travellers fondly imagine that on a well-appointed steamer they get distilled water to drink, but as a matter of fact most ships take in their water-supply without any regard to cleanliness from ports where the water-supply is known to be bad, such as, among others, Marseilles and Alexandria. Most steamers then filter it through antiquated filters which are probably useless. This is a sanitary question which needs investigation badly.

Cairo, April 14th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Graduation at the Army Medical School.

THE Army Medical School at Washington, D.C., which opened on Nov. 4th, 1901, closed its fifth session on April 4th, 1902, with its graduation exercises in the lecture-hall of the National Museum. Colonel W. H. Forwood, the president of the faculty, explained fully the course of study just completed by the class and announced the name of Assistant-Surgeon James M. Phalen as the member who had received the highest marks, entitling him to the Hoff Memorial Medal. The distinction of honour graduates was won by Assistant-Surgeons Conrad E. Koerper, Roderick P. O'Connor, and Robert U. Patterson, who had passed more than 90 per cent.; the majority of the students had made high percentages and none had fallen below the required rate, 70 per cent. The Secretary for War handed to each of the members of the class the diploma of the school, in the order of his rank in the army, and then the formal address of the occasion was delivered by the Surgeon-General. He emphasised the importance of preventive medicine in military practice and said that the important function of the Army Medical School was to familiarise the student officers with all that was known on this subject, to fit them to give expert advice on all matters relative to the prevention of disease in the ranks of the army serving under various conditions. The subject had become especially important since the Philippines had come into the possession of the United States, as the soldiers were now exposed to various infectious diseases which were either very rare or quite unknown in their own country. Almost every military post now offered facilities for bacteriological and chemical experiment and the members of this class would, it was expected, make the most of their opportunities, not only for the purpose of diagnosis in the patients' interest and of prophylaxis for the benefit of the command to which they belonged, but in the broader field of profit to scientific medicine and humanity in general.

An Experimental Hospital School.

An experiment as to the effect of certain foods upon the physical and mental development of children is now being conducted at the Chicago Hospital School for Nervous and Delicate Children. The main purpose of the research is to formulate if possible a dietary for children of from five to 15 years of age. Foods are prepared according to certain prescribed recipes, and the children are permitted to eat sparingly or generously as they themselves may choose. All foods are analysed before cooking, and later each child is served with carefully weighed portions best suited to his individual tastes, need, and capacity; the uneaten portion is weighed, so as to ascertain accurately the amount of food consumed. Each day the urine and fæces are carefully examined by medical men and the accompanying mental and physical phenomena are carefully watched and daily recorded to show the deviation from the normal. Special teachers and trained nurses make these observations. This school was founded two years ago and it serves as a pathological laboratory for the Chicago University, the only university that has a working pathological laboratory of this sort.

Deaths by Lightning in the United States.

Mr. Alfred J. Henry, professor of meteorology of the Weather Bureau of the United States Department of Agriculture, has published a bulletin relating to this subject. The number of persons killed by lightning during 1900 was 713; of this number 291 were killed in the open, 158 in houses, 57 under trees, and 56 in barns; the circumstances concerning the death of the remaining number are not known. To this may be added the number injured, which was 973. Professor Henry prepared a paper some time since on the relative frequency of fatalities by lightning in the several States and territories. He then recorded the statistics for a period of three years but thought best not to draw conclusions from them owing to the length of the time covered. In his recent bulletin he states that the number of fatalities must depend partly upon the frequency of the lightning strokes per unit area, also upon the density of the population and the character of the thunderstorms which traverse the region. Thunderstorms occurred with considerable frequency in that part of the United States east of the one-hundredth meridian, excepting a strip along the northern border. West of this section, not including the Rocky Mountains, the frequency of storms steadily diminished, practically reaching zero directly on the Pacific Coast. The largest number of fatalities occurred in the Middle Atlantic States; the Ohio Valley and Tennessee ranked second, and the Middle and Upper Mississippi Valleys filled the third place. During the years 1896-1900 the greatest number of deaths from lightning occurring in any one State were in Pennsylvania, 186; in Ohio, 135; and in Indiana, Illinois, and New York, 124 each. The greatest fatality from any one stroke occurred in Chicago, when 11 persons crowded together in a zinc-lined hut were killed instantly by one bolt.

Advancing the Educational Qualification of Medical Students.

Admission to the first-year class of the College of Physicians and Surgeons, New York City, has been thrown open to any student who complies with the minimum requirements for a medical student's certificate, as defined by the laws of the State of New York. A certificate is issued by the regents to any student applicant who presents 48 academic "counts" chosen from any subjects of secondary school study. The law provides that a student who has obtained 36 of these "counts" may enter upon the study of medicine, having one year in which to make good the remaining "counts." On and after September, 1903, no student will be admitted who has not obtained a medical student's certificate in one of two ways. He must have successfully completed at least one full year's course of study at some college or scientific school in the United States, or have pursued an equivalent course of study at some European institution, the question of the equivalence being determined by the regents of the University of the State of New York. The alternative is presented to the student of passing an entrance examination in June of any year held by the College Entrance Examination Board, or in September of any year held by the Committee on Entrance Examinations of Columbia University, or in part by both of these, provided only that if a portion of the examination be taken in June of any year the entire examination must be completed not later than in September of the following year.

Temperance Instruction in the Public Schools.

The national superintendents of schools in Chicago last year reported that the department of superintendence agrees cordially with the special advocates of the temperance cause in holding that everything that public instruction can do in the battle against intemperance ought to be done and that both physiology and hygiene should be so taught as to leave in the minds of children and youths as adequate and proper a knowledge of the effects of alcoholic drinks, stimulants, and narcotics on the human system as possible. Since the last meeting of this department there has been considerable discussion of the question as to whether alcohol under any conditions is properly to be defined as an article of food. Medical authorities are quoted in support of both sides of this question but no authority has been found to maintain that alcohol is a food in the ordinary sense of that term. The question of the supposed food value of alcohol is a technical one for medical experts to determine and not one which need concern the man or woman who is engaged in the work of public instruction of children and youth. For them it is enough to know that its use as a beverage may be injurious and that all authorities agree in deprecating the formation of the drinking habit.

Mr. Henry Merwin Shrady, son of Dr. George F. Shrady, editor of the *New York Medical Record*, has gained the first award in the competition of models which recently took place in Washington for the purpose of selecting a statue of General Grant to be placed in that city.

April 18th.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the second examination of the Board at the quarterly meeting of the examiners in the subjects indicated:—

Anatomy and Physiology.—Hugh William Acton, Middlesex Hospital; James Elrick Adler and Charles Sydney Archer, London Hospital; Frederic Charles Joseph Baker, St. Mary's Hospital; William Girling Ball, St. Bartholomew's Hospital; Ernest Charles Page Barnes, London Hospital; Hugh George William Beckett, St. Mary's Hospital; Samuel Lander Benton, University College, London; Albert Ogier Bisson, University of Lausanne, Switzerland; Albert Edward Blackburn, Yorkshire College, Leeds; Richard Osmond Bodman, University College, Bristol; John Taylor Bowker, Owens College, Manchester; Rowland Alessandro Bowling and Robert Henry Bott, St. Bartholomew's Hospital; Stanley Bott, London Hospital; James Rynd Briscoe, B.A. Camb., Cambridge University; John Bryan, London Hospital; Arthur Hill Burnett, Royal Colleges of Physicians and Surgeons, Edinburgh; John Graham Castellain, B.A. Cantab., St. George's Hospital; Charles Barett Deane Butcher and William Rex Collingridge, St. Bartholomew's Hospital; Vivyan Colmer, London Hospital; David Kirkpatrick Coutts and Reginald John Hands Cox, St. Thomas's Hospital; Arthur Douglas Crofts, Guy's Hospital; Claude Harold Cross, St. Bartholomew's Hospital; Frederick Spencer Davies, St. Thomas's Hospital; Langford George Davies, B.A. Cantab., Guy's Hospital; Percival Alfred Dingle, St. Bartholomew's Hospital; Alfred Dinnis, Charing Cross Hospital; Mohammed Omar Dollie, University College, London; Christopher Elliott, St. Bartholomew's Hospital; Trevor Evans, London Hospital; Harold William Farebrother, Charing Cross Hospital; George Edward Ferguson, St. Mary's Hospital; George Finch, Yorkshire College, Leeds; George William Morgan Fletcher, University College, Bristol; John Freeman, B.A. Oxon., Oxford University; Colin James Galbraith and Alexander Harold Gifford, King's College Hospital; Leonard Gray and John Purser Griffin, St. Bartholomew's Hospital; George Hamilton, Guy's Hospital; James Clarence Ledeatt Hingston, Middlesex Hospital; Edward Coomber Hobbs and Herbert Stanley Hollis, St. Mary's Hospital; Alfred Wyatt Hooker, St. Thomas's Hospital; Walter Goldie Howarth, B.A. Cantab., Cambridge University and King's College Hospital; James Bonnell Howell, University College, Cardiff; Richard Rossiter Huxtable, Charing Cross Hospital; Francis Samuel Jones, University College, Liverpool; Frederick Harold Lennox Jones, Guy's Hospital; George Francis Jones, University College, London; Khursedji Nasserwanji Karanjia, Grant Medical College, Bombay; James Reginald Kemp, St. Bartholomew's Hospital; Charles Frederic Kernot, London Hospital; George Johnson Langley, St. Thomas's Hospital; Arthur Edward Leapingwell and Farquhar Celynin Lloyd, St. Mary's Hospital; William Alfred Thomas Lloyd, London Hospital; Walter St. Claire McClure, Firth College, Sheffield; James Eustace Radclyffe McDonagh, St. Bartholomew's Hospital; Donald Grey MacGill, Owens College, Manchester; Clarence Basil McNeile, Middlesex Hospital; Conwy Llewellyn Morgan, St. Thomas's Hospital; Donald Macrae and John Findon Murphy, London Hospital; John Orrett Musson, Guy's Hospital; Reginald Cavan Neil, University College, London; Lionel Edward Close Norbury, St. Thomas's Hospital; Arthur Boniface O'Brien, Guy's Hospital; Geoffrey Ratcliffe Plaister, London Hospital; Vining Gedny, Joseph Paul, and Wilfred Hill Powell, St. Mary's Hospital; John Edward Prentis and William Percy Purdon, Guy's Hospital; Arthur George Laurence Reade, Charing Cross Hospital; Philip Alfred Reckless, Firth College, Sheffield; Max Balzar Reichwald, St. Bartholomew's Hospital; Vivian Ernest Ridewood, B.A. Lond., London Hospital; Henry Charles Samuel, University College, London; James Donald Sinclair, Edinburgh School of Medicine; Alfred Alexander Smith, Charing Cross Hospital; Armstrong Smith, Middlesex Hospital; Charles Maberley Stevenson, Cambridge University and Guy's Hospital; Thomas Stordy and Harold Foster Strickland, Charing Cross Hospital; James Herbert Sutcliffe, Yorkshire College, Leeds; Richard James Campbell Thompson, St. Thomas's Hospital; James Aubrey Torrens, St. George's Hospital; Harold Sugden Vivian, Middlesex Hospital; Harold Rosser Styleman Walford, St George's Hospital; John Wallace, B.A. Oxon., Oxford University and St. Thomas's Hospital; John Warburton, Owens College, Manchester; Howard Francis Warner, Prelim. Sci., M.B. Lond., London Hospital; Walter Welchman, Prelim. Sci., M.B. Lond., Guy's Hospital; John Allen Robertson Wells, St. Thomas's Hospital; Stanley Martin Wells, Guy's Hospital; Charles Francis Orr White, B.A. Cantab., Cambridge University; Clifford Sidney White, University College, London; Ralph Osmond Williams, Guy's Hospital; William Wynne Williams, King's College Hospital; William Sugden Williamson, Yorkshire College, Leeds; David Wilson, Prelim. Sci. Lond., St. Thomas's Hospital; Murray Richard Osmond Wilson, University College, Bristol; Harold Douglas Wyatt, Guy's Hospital.

Anatomy only.—John William Wynne Hogan, Madras Medical College and St. Bartholomew's Hospital.

UNIVERSITY OF DURHAM.—At the third examination for the Degree of Bachelor in Medicine held in April the following candidates satisfied the examiners:—

Second-class Honours.—Reginald Bigg, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital.

Pass List.—Frederick Durnford Atkins, St. Thomas's Hospital; Frederick George Armstrong, College of Medicine, Newcastle-upon-Tyne; John Arthur Bell, St. Bartholomew's Hospital; Harold Linton Currie, College of Medicine, Newcastle-upon-Tyne; Margaret Douglas French, London School of Medicine for Women

William Gibbons and Alfred Herbert Heslop, College of Medicine, Newcastle-upon-Tyne: Walter Haward, St. Thomas's Hospital; Thomas Charles Hunter, College of Medicine, Newcastle-upon-Tyne; William Hughes, Edinburgh School of Medicine; William Henry Peacock and William John Phillips, B.Sc., College of Medicine, Newcastle-upon-Tyne; Donald Murray Ross, St. Thomas's Hospital; Mary Raw, Constance Charlotte Robertson, David Rees Roberts, Fred Stoker, and Andrew Smith, College of Medicine, Newcastle-upon-Tyne; Thomas Young Simpson, M.R.C.S., L.R.C.P., London Hospital; John Malcolm Shaw, College of Medicine, Newcastle-upon-Tyne; Otho Boyle Travers, Guy's Hospital; and William Frank Wilson, College of Medicine, Newcastle-upon-Tyne.

University of Cambridge.—At a congregation held on April 24th the following medical degrees were conferred:—

Doctor of Medicine.—H. B. Roderick, Emmanuel; A. C. Jordan, Sidney-Sussex.

Bachelor of Medicine.—F. H. M. A. Beckett, Selwyn Hostel.

University of Edinburgh.—The following is the official pass-list at the recent professional examinations for degrees in medicine and surgery:—

First Professional Examination.—Mukhtar Ahmed, B.A., R. G. A. Bagnall, E. H. Black, C. E. Blair, George Blair, I. W. Brebner, S. T. Champtaloup (with distinction), W. I. M. Clark, Agnes M. Cowan, F. S. Cumming, Richard B. Davidson, A. M. Dick, M. G. Dill, A. M. Drennan (with distinction), Robert Duncan, James Dundas, E. W. Dyer, S. S. Dykes, Mary S. Finlayson, C. N. Finn, M. S. Fraser, W. G. Frohlich, G. F. Gallagher, W. J. Geale, Laurence Gibson, G. A. Gordon, M. C. R. Grahame, Joseph Green, J. C. Grieve, G. F. Grogan, George Gunn, Mary D. Hancock, A. J. Harper, A. S. Hendrie, H. S. A. Hogg, F. O. Inglis, R. F. Johnson, H. C. Johnston, W. L. Johnston, R. Lloyd Jones, Alexander M'Donald, D. F. Mackenzie, John B. Mackenzie, I. R. Macleod, George M'Mullan, A. C. B. M'Murtrie, W. J. MacNab, A. S. Mactavish, J. N. M'Turk, David Mann, G. M. Melville, Hugh Millar, F. C. Mills, B.A., John Morris, Janet M. Murray, J. K. Murray, R. H. Nolan, Ethel A. Olchard, J. S. Orwin, A. S. Paterson, H. B. Porteous, C. A. Purnell, G. Y. Richardson, W. H. Riddell, W. R. Ridley, W. G. Rivers, R. M. Robb, W. G. Robertson, Frank Ross, Alexander Sandison, James Scott, T. H. Scott, H. L. Sells, H. G. Smith, A. G. V. van Someren, H. V. Taylor, W. A. A. Taylor, J. A. R. Thompson, Annie D. Urquhart, V. S. Vallathan, B.A., Philip Vickerman, R. H. Walton, Andrew Wight, W. E. R. Williams, and J. T. D. Young.

Second Professional Examination.—R. G. W. Adams, E. A. Aylward, J. W. H. Babington, J. M. Barkley, R. B. Barnetson, Benjamin Baty, W. P. Beattie, Douglas Bell, L. H. I. Bell, A. R. Berrie, J. M. Beyers, A. S. L. Biggart, F. T. Bowerbank, David Brown (with distinction), T. B. Carlyle, V. T. Carruthers, Mildred M. L. Cathels, J. W. Cathles, G. S. Clark, M.A., A. G. Coullie, James Craw, W. B. Cullen, George Cunningham, W. H. Cusack, J. M. Darling, J. R. Dobbin, C. E. Dumanoire, T. H. Easton, N. C. Fischer, J. M. R. Flamet, N. C. Forsyth, R. H. Fothergill, Louis Fourie, A. N. Fraser, W. J. Fraser, Laurence Gavin, N. J. H. Gavin, H. M. Gillespie, A. G. Glass, M.A., William Godfrey, J. M. Graham, W. W. Greer, John Grieve, P. A. Harry, Ephraim Henderson, M.A. (with distinction), A. W. Hogg, Jean S. Hogg, R. B. Hole, G. S. Husband, K. U. A. Inniss, Ada Jackson, William Jarvis, S. A. Johnston, J. H. H. Joubert, John Kirk, G. F. S. Landok, S. W. S. Leary, A. J. Lewis, James Lochhead, M.A. (with distinction), J. B. Lockerbie, A. D. M'Callum, John MacDonald, J. P. M'Gowan, M.A., H. R. Macintyre, R. J. Mackessack, Amy M. Mackintosh, D. P. Marais, Aimée E. Mills, M.A., B.Sc., L. S. Milne, T. B. Mouat, W. M. Mumby, D. S. Murray, Claude O'Flaherty, Archibald Oliver, C. D. O'Neal, E. G. S. Orbell, Garfield Ormrod, Florence M. S. Price, H. S. Reid, Margaret H. Robertson, Shiela M. Ross, C. S. Ryles, F. R. Sinton, L. H. Skene, C. J. Smith, G. M. C. Smith, W. A. Wilson Smith, R. A. L. van Someren, Patrick Steele, Hugh A. Stewart, A. C. Strain, K. A. Moody Stuart, Annie F. Theobalds, H. M. Thompson, Rose C. Townend, G. H. Usher, F. L. de Verteuil, R. W. L. Wallace, D. C. Welsh, D. P. D. Wilkie, F. A. Wille, W. B. Wishart, C. H. Wright and Margaret C. Young.

Third Professional Examination.—R. T. G. Aickin, Daniel Allison, J. A. Anderson, W. W. Anderson, F. L. Atkinson, Agnes Balfour, C. M. Begg, A. W. Beveridge, T. C. Blackwell, John Brennan, Edith C. Brown, J. E. M. Brown, G. L. Brunton, Agnes Buchanan, Harry Caird, T. P. Caverhill, R. A. Chambers (with distinction), Katherine J. S. Clark, Elizabeth L. Colby, C. H. Craig, R. W. Craig, C. S. Crichton, D. M'K. Crooks, D. Halliday Croom, F. D. Crosthwaite, W. B. A. K. Cullen, Arthur Dangerfield, J. M. Darling, H. S. Davidson, James Davidson, W. H. Davison, D. E. Derry, A. C. Devereux, J. M. Dewar, James Donaldson, M.A., A. M. Dryden (with distinction), Alice M. Ebden, G. J. Earle, John Findlay, H. N. Fletcher, John Fortune, C. R. Gibson (with distinction), F. H. Gibson, J. D. Giles, James Girdwood, J. M. Glasse, Alexander Gray, M.A., Elizabeth C. Gunn, A. Mabel Gurney, A. A. Hall, M.A., C. R. F. Hartley (with distinction), G. W. Harty, George Henderson, A. E. Hodgson, A. F. Hughes, J. P. P. Inglis, J. M. Johnston, R. W. Johnstone, J. H. Jones, J. H. Kay, J. W. Keay, Ivan C. Keir, E. A. King, J. M. Kirkness, L. A. H. Lack, F. T. C. Linton, M.A., C. D. Lochrane, Isabella Logie, J. M. Lovett, Alexander Lundie, Henry MacCormac, J. R. M'Gregor, N. D. Mackay, T. A. MacKenzie, Violet C. M'Laren, William MacLaren, J. J. M'Millen, J. B. M'Neill, I. M. Macrae, H. C. Martin, R. H. Martin, P. W. Mason, A. G. M. Middleton, A. S. Millard, G. H. S. Milln, W. S. Milne, C. R. P. Mitchell, G. I. Moriarty, C. H. Muller, H. L. Munro, D. M'K. Newton (with distinction), Thomas Nicol, W. H. Nutt, D. D. Paton, M.A., Thomas Peebles, J. A. Pottinger, Julius L. Pringle, W. L. Pritchard, William Readman, Eva A. Robertson, W. Sibbald Robertson, Amy Robinson, L. C. Robinson, J. A. Ross, Mabel Ross, J. A. Roux, N. C. Rutherford, D. G. Addison Scott, D. J. Scott, J. E. Scott, M.A., W. M. Selby, G. H. Skinner, J. H. Smith, S. W. Smith, E. W. Smyth, Eva M. Snowball, Effie Stuart, John Tait, J. E. Taylor, T. T. Thomson, G. C. Trotter, E. A. Turpin, Robert Veitch, J. A. L. Wallace, W. R. S. Watkins, G. J. Wentzel, Leonard West, R. M. Manwaring White, C. H. Wright, B.A., W. D. Wright (with distinction), and G. W. Young.

Third Professional Examination (New Regulations—Pathology only).—Samuel Burns, M.A.

Conjoint Board of the Royal Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow.—At the April meetings held in Glasgow the following candidates passed their respective examinations:—

First examination (five years' course).—Fred. Miller Murray, Glasgow; Frederick Barnes Elwood, Belfast; Andrew Ford Garrand, Glasgow; John Wm. Nelson Roberts, Wales; Frederic James Breakell, Preston; Evan Alan S. Shaw, Callao; and Edward Francis Nyhan, Dunmanway.

First examination (four years' course).—John Stothart Farries, Dumfriesshire; Alexander Jack, Co. Antrim; and George Munro MacLeod, Edinburgh.

Second examination (five years' course).—George Hart, Parkhead; Charles Chaves, Bombay; Archibald Frank Spinks, Partick; Alexander Robb M'Intyre MacIlraith, Cathcart; William Wallace Dempster, Dublin; Samuel Robert Scott, Co. Down; Edward Ernest Murphy, Co. Cork; Evelyn Morris Franklin, Co. Cork; and Frederick Wm. March, Bradford.

Second examination (four years' course).—Adam Ardill, Co. Tipperary; and Joseph Edmund Mullan, Coleraine.

Third examination.—Alexander Allan, Dennistoun (with distinction); Robert Septimus Walker, Sunderland; Reginald Norman Macdonald, Buenos Ayres; William Robert Addison Coates, York; Harry Armstrong, West Hartlepool; John Bertram L. S. Scott, Manchester; Dennis Woodley Purkis, Cambridge; Lizzie Denny, Reading; and William Douglas Cockburn, Catrine.

Final examination (and admitted Licentiates of the three Colleges).—Henry Leighton Jones, New South Wales; Thomas Weir M'Cubbin, Glasgow; William Thomson, Glasgow; Edwin Norman de Vere Dawson, W. Kensington; Henry Solomon, Manchester; Stanley Lister G. D. Maclaine, Uddingston; Charles Vaughan Craster, Stevenage, Herts; William Henry Duncan, Maryhill; Hugh Williams, Talysarn, Wales; Terence Aloysius Welch, Dodington, Whitchurch, Salop; and Patrick Carroll, Kildonery, Co. Cork.

Foreign University Intelligence.—*Berlin:* Dr. E. Opitz has been recognised as *privat-docent* of Gynæcology, Dr. M. Ficker as *privat-docent* of Hygiene, Dr. Richard Henneberg as *privat-docent* of Neurology and Psychiatry, and Dr. K. Kaisering as *privat-docent* of Physiological Anatomy.—*Budapest:* Dr. Leo Liebermann has been promoted to the chair of Hygiene in succession to the late Dr. von Fodor.—*Jena:* Dr. H. Eggeling of Strasburg has been recognised as *privat-docent* of Anatomy.—*Lille:* Dr. Carlier has been appointed to the chair of External Pathology.—*Lyons:* Dr. Jaboulay has been appointed to the chair of Clinical Surgery.—*Naples:* Dr. C. Grossi has been recognised as *privat-docent* of Medical Pathology and Dr. Ceraso as *privat-docent* of Otology.—*Pavia:* Dr. G. Masnata of Palermo has been recognised as *privat-docent* of Operative Medicine.—*Philadelphia Polyclinic:* Dr. Geo. C. Stout has been appointed to the chair of Otology, in succession to Dr. Alex. Randall, resigned.—*Pisa:* Dr. Carlo Fedeli, Extraordinary Professor, has been promoted to the Ordinary Professorship of Medical Pathology; Dr. Baldi has been promoted to the Ordinary Professorship of Materia Medica and Pharmacology.—*Prague (Bohemian University):* Dr. R. Kimla has been recognised as *privat-docent* of Pathological Anatomy.—*Turin:* Dr. O. Modica has been recognised as *privat-docent* of Forensic Medicine.

Deaths of Eminent Foreign Medical Men.—The deaths of the following eminent foreign medical men are announced:—Dr. Adolf Jarisch, Extraordinary Professor of Dermatology and formerly assistant to Professor Hebra in Vienna. His age was 52 years.—Dr. Heinrich Lahs, Extraordinary Professor of Gynæcology in the University of Marburg.—Dr. Crouzat, Professor of Clinical Midwifery in Toulouse.—Dr. Moritz Kaposi, Professor of Dermatology in the University of Vienna, at the age of 65 years. He was assistant to Professor Hebra and ultimately succeeded him. His publications on Dermatology are numerous and well known.—Dr. J. T. Metcalfe, formerly Professor of Medicine in the New York College of Physicians and Surgeons.—Dr. C. H. Burnett, Professor of Otology in Philadelphia.—Dr. Münde, Professor of Gynæcology in New York.—Dr. Christian Fenger, Professor of Surgery in the Rush Medical College, Chicago.—Dr. Bouqué, Professor of Surgical Pathology in the University of Ghent.—Dr. J. Lazarevich, formerly Professor of Midwifery, Gynæcology, and Children's Diseases in the University of Kharkoff. He died at St. Petersburg, aged 72 years.—Professor Ivan Balinski, formerly Professor of

Mental Diseases in the Medico-Chirurgical Academy of St. Petersburg.—Dr. G. Inzani, formerly Professor of Pathological Anatomy in the University of Parma.—Dr. Mott Moore, a well-known surgeon of Buffalo.—Dr. W. W. Johnston, formerly Professor of Medicine in the Columbian University, Washington.—Dr. Cushing, Lecturer on Gynæcology in Long Island Hospital, Brooklyn.—Dr. George M. Warner, Professor of Materia Medica and Therapeutics in the Louisville Medical College.—Dr. Josef Schöbl, Professor of Ophthalmology in the Bohemian University, Prague.—Dr. Robert, a Barcelona physician.—Dr. Bruzelius, formerly Professor of Pathology and Therapeutics in the Stockholm Medical School.

CHILDREN'S FRESH AIR MISSION.—The annual meeting of the Children's Fresh Air Mission was held in the great hall of the Charterhouse on April 29th, when the Master of the Charterhouse, the Rev. Dr. Haig Brown, presided. The report stated that last year 3293 children from very poor districts of London, chiefly Clerkenwell, St. Luke's, and Holborn, had been sent to the country for a week or more at a total cost of £2126. The parents themselves had contributed £464. The Bishop of Bristol, who proposed the adoption of the report, said that this mission, by giving children a taste of rural life, tended to help a movement which was absolutely necessary—a dispersion of London's overcrowded population into the country.

BARROW HOSPITAL.—Judge Parry's report concerning charges made against the management of the North Lonsdale Hospital was read at a meeting of the hospital council on April 16th. He found that the statements made to the guardians about a patient named Owens by Dr. D. H. Anderson were incorrect in fact. "Owens made statements to Dr. Anderson which the latter repeated in good faith," and "the hospital management did only what was correct" in the case. He stated also that the cases of delay in being seen by the house surgeon seemed to have been unavoidable "and there was no evidence that any of them had sustained injury by delay." As to two complaints of treatment, Mr. W. P. Montgomery of the Manchester Infirmary, the surgical assessor, reported that the treatment was correct. The honorary staff of the hospital considered that, except on comparatively rare occasions, there was no occasion for two house surgeons and the judge stated that Mr. Montgomery concurred with them, but he thought it advisable that the council should consider the matter. In the two cases referred to he stated that a night nurse had been reprimanded and that no blame attached to the council or house surgeon. In the second case there was a claim for wrong treatment by the house surgeon of which there was no evidence and the council "most unwisely" paid the man £15. In conclusion, the judge suggested that the council meetings should be held weekly instead of monthly and that the yearly accounts should be set out in greater detail. He said that "in his opinion the hospital is in every way efficient and the results of the treatment most creditable to the staff."

THE ROYAL INSTITUTION.—X Rays and Localisation formed the subject of the Friday evening discourse delivered at the Royal Institution on April 25th by Mr. J. Mackenzie Davidson. In speaking of the photographic use of the rays he said that the definition of a photograph taken with them depended on the relation of the cathode and the anti-cathode in the vacuum tube. The rays originated at the point where the cathode stream met a solid—namely, at the anti-cathode, but the anti-cathode did not stop all the stream, part of which passed on till it encountered the glass walls of the tube, when there was a further production of x rays, although of a less powerful quality. The rays therefore radiated from a comparatively large surface and the sharpness of the shadows was interfered with, but better definition could be obtained when the circumferential rays were intercepted by surrounding the tube with a compound of lead which could be scraped away at the point where it was desired that the rays should emerge. There were considerable differences between the effects produced on sensitive photographic surfaces by the x rays and by ordinary light. If the hand was laid upon a pile of six ordinary sensitive films the x rays would give a picture on each of them, the distinction between that on the uppermost and on the undermost film being very slight, and several such negatives might sometimes be combined when a positive was to be taken. If a plate was given a short exposure to ordinary light before a picture was taken on it with x rays no special effect was produced beyond some fogging of the plate but if the short exposure to ordinary light followed the taking of the x-ray picture the developed photograph was reversed. This curious phenomenon had been studied not only in this country but also by Professor Nephir in America. Mr. Davidson showed this experiment. The figure of a crown cut out in a flat piece of thin lead supported on a sheet of cardboard was laid on a sensitive plate contained in a light-proof envelope and an exposure of two minutes to the x rays was given. The plate was then completely uncovered and exposed to the ordinary illumination of the room for five minutes, after which it was developed and the figure of the crown was seen to be black on a light background. The method of photographing metallic objects embedded in the human body was also shown, as well as the "cross-thread localiser" for ascertaining the depth of penetration.

VACCINATION GRANT.—Mr. T. Messenger, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has received the vaccination grant as public vaccinator for Bowness district of the Wigton Union, Kirkbride, near Carlisle.

LITERARY INTELLIGENCE.—Messrs. Longman are about to issue a new work by Dr. G. V. Poore, entitled "The Earth in Relation to Contagia." This volume will include the Milroy Lectures of 1899, together with papers on the Sanitation of Camps, on the Disposal of Slop-water, and on Milk in Relation to Disease.

FRENCH HOSPITAL DINNER.—The thirty-fourth annual dinner in aid of the funds of the French Hospital in Shaftesbury-avenue took place on April 26th at the Hotel Cecil, the French Ambassador, M. Paul Cambon, being in the chair, supported by the Lord Mayor, the Belgian Minister (Baron Whetnall), the Swiss Minister (M. Bourcart), the Servian Minister, and other members of the diplomatic and consular services. The Chairman, in proposing the toast of the evening, mentioned in terms of regret that the hospital had lost a warm friend and devoted officer in the person of the late Sir William Mac Cormac, Bart., K.C.B., K.C.V.O., who was for so many years honorary surgeon to the hospital. He spoke highly of the services rendered by Mr. Edmund Owen and Dr. George Ogilvie, and he said that it was his pleasure for the fourth time to sing the praises of Dr. Vintras whose two children—the hospital and the convalescent hospital at Brighton—were now well on their feet. He added that the French Government had made a donation of 100,000 francs to the funds which he hoped would largely benefit by the fêtes which were shortly to be held at Earl's Court under the patronage of the Prince and Princess of Wales, thus enabling them to clear off their debts and to place the institution on a firmer basis. The musical programme, which was deferred until after the toast-list had been exhausted, comprised songs by Madame Hélène Palacek, Signor Umberto Salvi, Miss Florence Venning, and Mr. G. Hodgson, under the direction of Chevalier Tito Mattei.

Parliamentary Intelligence.

HOUSE OF COMMONS.

THURSDAY, APRIL 24TH.

Medical Provision in the Scottish Highlands.

MR. WEIR asked the Lord Advocate if he would state the number of parochial medical officers in each of the six crofting counties who did not possess the public health diploma required under the Public Health Act, 1897, and if he would state why the Local Government Board for Scotland continued to confirm the appointment of medical officers in Highland crofting counties regardless of the conditions imposed by statute.—The LORD ADVOCATE replied: The Secretary for Scotland is informed by the Local Government Board that the figures are as follows: Argyll County, 23 local medical officers, of whom three possess the statutory qualification; Inverness County, 10 local medical officers, of whom one possesses the statutory qualification; Ross and Cromarty, 11 local medical officers, of whom two possess the statutory qualification; Sutherland County, no local medical officers; Caithness County, no local medical officers; Orkney and Shetland, three local medical officers, none of whom possess the statutory qualification. The medical officers who do not possess the public health diploma were appointed prior to the coming into operation of the Public Health (Scotland) Act, 1897 and consequently do not require to possess the qualification. The Local Government Board does not recognise new appointments of medical officers who do not possess the statutory qualification.

Poor-law Nursing in Ireland.

DR. E. C THOMPSON asked the Chief Secretary to the Lord Lieutenant of Ireland if he was aware of the dissatisfaction which existed in Ireland with the qualifications required by the Local Government Board for district hospital nurses; and if he would appoint a small independent committee to consider the question.—Mr. WYNDHAM replied that he was prepared to consider the advisability of appointing such a committee, though he could not pledge himself to do so. The reforms which had been instituted by the Local Government Board had produced very satisfactory results and he would not like to do anything which would prejudice the work of the Board in this connexion.

The Conscientious Objector.

Two questions were addressed to the Home Secretary with regard to the action of magistrates at Beccles and Grimstone in refusing certificates of exemption to applicants who declared that they had conscientious objection to vaccination and in each case Mr. RITCHIE said that he had no power to interfere.

FRIDAY, APRIL 25TH.

Medical Officers of Health.

On the motion of Sir FRANCIS POWELL a Bill was introduced and read a first time "to amend the law relating to the qualification and tenure of office of medical officers of health and inspectors and to make further provisions relating to superannuation allowances for such officers and inspectors, and for other purposes."

MONDAY, APRIL 28TH.

Ophthalmia and Ringworm in Poor-law Institutions.

Mr. FLOWER asked the President of the Local Government Board if he could state the number of children at present suffering from ophthalmia and ringworm respectively in metropolitan Poor-law schools and institutions.—Mr. LONG replied: According to the latest information in my possession the number of children suffering from ophthalmia and ringworm respectively was 413 and 325 in metropolitan Poor-law schools and 351 and 294 in metropolitan workhouses and infirmaries.

TUESDAY, APRIL 29TH.

London Water Charges.

Mr. WEIR asked the President of the Local Government Board whether he was aware that the West Middlesex Water Company had quite recently raised its charges to consumers, and seeing that a Bill for dealing with the London water-supply was now before Parliament would he state whether any other metropolitan water companies had also raised their charges since the introduction of that Bill, and, if so, would he give their names.—Mr. LONG replied: I am informed that from Christmas last the company referred to has reduced the rebate which since 1894 it has allowed on water charges from 10 per cent. to 5 per cent. The alteration is stated to have been rendered necessary owing to the payment which the company has to make to the City Chamberlain under its Act of 1894 and to increased rates and charges for labour and materials. Notice of the alteration was sent to the local authorities in the district on Nov. 1st and an explanation is printed on all the application papers. I am not aware whether any other of the metropolitan water companies have recently raised their charges.

Sickness on Board a Training-ship.

Mr. ARNOLD-FORSTER, in reply to a question by Mr. KEARLEY, said that there had been a considerable amount of sickness among the boys on board the training ship *Impregnable* at Devonport. There had been an epidemic of scarlet fever in a mild form but he was glad to say that it was on the decline. In February last, in view of the presence of scarlet fever, a rigid inspection of the ship was made by the Inspector-General of Plymouth Hospital who reported that the sanitary conditions were in every way satisfactory and that disinfection was being carried out in a very efficient manner. The last case of scarlet fever occurred on April 21st, and in view of the decline in the number of cases and of the rigorous measures which had been taken to disinfect the ship it was hoped that the disease might have been stamped out. Should this prove not to be the case further measures would be taken for the protection of the health of the boys.

Disease in the Island of St. Kitts.

Mr. PIRIE asked the Secretary of State for the Colonies if the inhabitants of St. Kitts had petitioned that prisoners of war should be confined there and if the Governor had supported that petition; and could he state if prisoners were confined there and if troops had been sent there to guard them; was he aware, according to the report issued from the London School of Tropical Medicine, that every third person in the island was suffering from filariasis which was an early stage of elephantiasis; and would this matter receive his attention in coming to any decision on the matter.—Mr. CHAMBERLAIN, in reply, said: Some leading residents in St. Kitts have suggested that Boer prisoners might suitably be sent to that island, but the Governor has not endorsed the request and no prisoners or troops have been sent nor is there any present intention of sending them.

Cremation Bill.

The Grand Committee on Law met to-day for the consideration of the Cremation Bill, a measure designed to enable burial authorities to establish crematoria and to provide for the proper regulation of the burning of human remains In Clause 4 an amendment was made requiring the site as well as the plans of a projected crematorium to be approved by the Local Government Board. As Clause 5 came before the Committee it proposed that no crematorium should be constructed nearer to any dwelling-house than 200 yards except with the consent in writing of the owner, lessee, and occupier of the house, and Mr. H. D. GREENE moved to add to this the words, "nor within 50 yards of any public path or way nor in the consecrated part of the burial-ground of any burial authority." After some discussion the Committee accepted this addition to the clause. Clause 7 directs the Home Secretary to make regulations prescribing in what cases and under what conditions the burning of human remains may take place.—On the motion of Mr. GREENE words were inserted in this clause requiring the Home Secretary to make regulations as to the disposition or interment of the ashes.—Mr. JACOBY raised the question of the danger of poisoning cases escaping detection, and Mr. JESSE COLLINGS, speaking as the representative of the Home Office, assured the hon. Member that in framing the regulations the department would keep this matter in view and require every possible precaution to be taken.—On the motion of Mr. GREENE a new clause was inserted to secure that the incumbent of an ecclesiastical parish shall not, with respect to his parishioners or persons dying in his parish, be under any obligation to perform a funeral service before, at, or after the cremation of their remains.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number*

BOND, F. T., M.D. Lond., has been re-appointed Medical Officer o Health to the Tetbury Urban District Council.

BROUGH, DANIEL, M.B., C.M. Edin., L.R.C.P. Lond., M.R C.S., has been appointed Deputy Medical Officer of Health for the Borough of Devonport.

BROWN, H., M.B., Ch.B. Vict., has been appointed Resident Obstetric Officer to the General Infirmary, Leeds.

BROWNE, A. E N., L.R.C.P. & S. Edin., has been appointed Acting Visiting Surgeon, *pro tem.*, to the Gaol at Wagga Wagga, N.S.W.

CLARKSON, W., L.R.C.P. Edin., L.F.P.S. Glasg., has been appointed Medical Officer of Health to the Morpeth District Council.

DODGSON, H., M.B., Ch B. Edin., has been appointed Senior Assistant Medical Officer to the Cumberland and Westmorland Asylum.

ELDER, J. B., M B., Ch.B. Aberd., has been appointed Junior Assistant Medical Officer to the Cumberland and Westmorland Asylum.

GAMBLE, M. F., L.R.C.S. Edin., has been appointed Medical Superintendent, *pro tem.*, of the Ballarat Lunatic Asylum, Victoria, N S.W.

HEARNE, W. W., M.B. Vict., has been appointed Public Vaccinator, *pro tem.*, for the North-Eastern Vaccination District of Victoria. N.S.W.

HINGSTON, CHARLES ALBERT, M D., B.Sc. Lond., M.R.C.S., has been appointed Honorary Physician to the Crownhill Convalescent Home, near Plymouth.

HONMAN, ANDREW, M R.C.S., has been appointed Certifying Medical Practitioner for the purposes of the Factories and Shop Acts at Williamstown, Victoria, N.S.W.

JONES, HERBERT, L.R.C.S. Irel., L.S.A., has been appointed Medical Officer of Health for the Bromyard Urban District.

LAIRD, ANDREW J., M.D., D.P.H., Assistant Medical Officer of Health for the County of Lanark, has been appointed Medical Officer of Health for the Borough of Crewe.

LEMARCHAND, ARTHUR WHARTON, L.R.C P. Lond., M.R.C.S., has been appointed Honorary Medical Officer to the North Devon Infirmary, Barnstaple, vice Dr. Mark Jackson, resigned.

LYNCH, PETER, L.R.C.P., L.R.C.S. Edin., has been appointed Certifying Medical Practitioner for the purposes of the Factory and Shop Acts at Carlton, Victoria, N.S.W.

MELLAND, CHARLES HERBERT, M.D. Lond., M.R C.P., has been appointed Honorary Physician to the Ancoats Hospital, Manchester.

MUIR, W. C. C., M.B. Glasg., has been appointed Medical Officer of Health for the Shire of Alberton, Victoria, N.S.W.

MULLEN W. L., M.D. Melb., has been appointed Medical Superintendent *pro tem.*, to the Yarra Bend Lunatic Asylum, Victoria, N.S.W.

PARK, J. S., L.R.C.P. Lond., has been appointed Officer of Health for the Shire of Cranbourne, Victoria, N.S.W

PEIPERS, F., M.D. Berl., has been appointed Officer of Health for the Shire of Korong, Victoria, N.S.W.

STEVENSON, ROBERT, M.D., has been appointed Medical Officer of Health to the Bootle Postal District.

TIPPETT, SYDNEY G., M.B. Lond., has been appointed Assistant Surgeon to St. Bartholomew's Hospital, Chatham.

TURNER, A. F., L.R.C P , L.R.C.S. Edin., has been re-appointed Medical Officer of Health to the Tewkesbury Corporation.

WALLACE, J. SIM, M.D., D.Sc., L.D.S. Eng., has been appointed Honorary Dental Surgeon to the West End Hospital for Diseases of the Nervous System.

WILLIAMSON, R. T., M.D., F.R.C.P. Lond., has been appointed Honorary Assistant Physician to the Manchester Royal Infirmary.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—Resident Surgical Officer. Salary £100 per annum, with apartments, board, and attendance.

BIRMINGHAM AND MIDLAND EAR AND THROAT HOSPITAL, Edmund-street.—Surgeon.

BRADFORD ROYAL INFIRMARY.—Junior House Surgeon, unmarried. Salary £50 per annum, with board and residence.

CANCER HOSPITAL, Fulham-road, S.W.—Junior House Surgeon. Salary at rate of £70 per annum, with board and residence.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Registrar. Honorarium of 20 guineas per annum.

CORNWALL ROYAL INFIRMARY.—House Surgeon (unmarried). Salary £100, increasing, with board and apartments.

DUDLEY, THE GUEST HOSPITAL.—Assistant House Surgeon for six months. Salary £40 per annum, with residence, board, and washing.

FISHERTON ASYLUM, Salisbury.—Assistant Medical Officer, unmarried. Salary £150 per annum, with board, lodging, and washing.

HOSPITAL FOR DISEASES OF THE THROAT, Golden-square, W.—Senior Clinical Assistant.

HOSPITAL FOR WOMEN, Soho-square.—Clinical Assistantships.

KENT COUNTY ASYLUM, Barming Heath, Maidstone.—Fourth Assistant Medical Officer and Pathologist, unmarried. Salary £175 per annum, rising to £200, with quarters, attendance, &c.

Kincardine, Ross-shire, Parish Council.—Resident Medical Officer. Salary £72 10s. as Medical Officer and £5 per annum as Vaccinator, with lunacy fees in addition.

Kings Norton and Northfield Urban District Council and Infectious Diseases Hospital.—Medical Officer of Health and Medical Superintendent. Combined salary £500 per annum.

Liverpool, David Lewis Northern Hospital.—Assistant House Surgeon. Salary £70 per annum, with board and residence.

Liverpool Stanley Hospital.—Senior House Surgeon. Salary £100 per annum, with board, residence, and washing; also Third House Surgeon. Salary £70 per annum, with board, residence, and washing.

Miller Hospital and Royal Kent Dispensary, Greenwich-road, S.E.—Junior Resident Medical Officer. Salary £80 per annum, with board, attendance, and washing, and prospect of re-election as Senior (salary £100).

Norfolk and Norwich Hospital.—Assistant House Surgeon for six months. Honorarium £20, with board, lodging, and washing.

North-West London Hospital, Kentish Town-road.—Resident Medical Officer. Also Assistant Resident Medical Officer, each for six months. Salary at rate of £50 per annum, with board, residence, and washing.

Royal Albert Hospital, Devonport.—Resident Medical Officer. Salary £110 per annum, with board and lodgings.

St. Giles, Camberwell Workhouse, Constance-road, East Dulwich.—Locum Tenens for the Medical Officer for four weeks. £4 4s. per week, with board and residence.

St. Mary's Hospital, Paddington.—Surgeon-in-Charge of Out-patients.

Seamen's Hospital Society, Greenwich.—Surgeon; also Honorary Anæsthetist.

Suffolk General Hospital.—House Surgeon. Salary £100 a year, with board, lodging, and washing.

Tottenham Hospital.—House Surgeon. Salary £50 per annum, with board, residence, and laundry.

Tunbridge Wells General Hospital.—House Surgeon, unmarried. Salary £125 per annum, with board, apartments, and attendance.

Wandsworth and Clapham Union, Home for Aged and Infirm, Church-lane, Tooting.—Assistant Medical Officer, unmarried. Salary £100 per annum, rising to £120, with apartments, board, and lodging.

Western General Dispensary, Marylebone-road, N.W.—Second House Surgeon, unmarried. Salary £80 a year, with board, residence, and laundry.

West Riding Asylum, Wakefield.—Pathologist and Assistant Medical Officer. *Salary £140, rising to £160, with apartments, board,* washing, and attendance.

Weymouth and Melcombe Regis Urban District Council.—Medical Officer of Health. Salary £300 per annum.

Wigan Infirmary.—Junior House Surgeon. Salary £80 per year, with apartments and rations.

Worcester General Infirmary.—House Physician, unmarried. Salary £70 per annum, with board, residence, and washing.

Births, Marriages, and Deaths.

BIRTHS.

Buzzard.—On April 28th, at Grosvenor-street, W., the wife of E. Farquhar Buzzard, M.B. Oxon., M.R.C.P. Lond., of a son.

Jackson.—On April 24th, at Carntyne, Hexham, Northumberland, the wife of John A. Jackson, M.D. Glasg., of a son.

Lemon.—On April 28th, at Burnt Ash-road, Lee, Kent, the wife of Edward Henry Lemon, M.R.C.S., L.R.C.P. Lond., of a son.

Rubel.—On the 18th inst., at the Red House, River, Dover, the wife of J. L. Rubel, M.R.C.S., of a daughter.

MARRIAGES.

Bothwell—Stumke.—On Thursday, March 27th, at Bulawayo, by the Rev. J. G. Aldridge, George Granville Bothwell, M.B., C.M. University Aberdeen, eldest son of the late G. G. Bothwell, M.R.C.S., L.R.C.P., of Topsham, Devonshire, England, to Stella, eldest daughter of Charles August Stumke, of Uitenhage, Cape Colony.

Carre—Montgomerie-Fleming.— On April 23rd, at St. Mary's Episcopal Church, Glasgow, Henry Carre, L.R.C.P., L.R.C.S. Irel., to Elisabeth Tennent, eldest daughter of the late J. B. Montgomerie Fleming, of Kelvinside.

Cobbledick—Whitton.—On April 24th, at St. Luke's Church, W. Hampstead, London, N.W., by the Rev. J. Salwey, Arthur Stanbury Cobbledick, M.D., B.S. Lond., M.R.C.S., L.R.C.P. Eng., second son of John Osborn Cobbledick, of Lyndhurst, Clifton, Bristol, to Jessie, the fourth daughter of William Whitton, of Springfield, Stradbally, Queen's co., Ireland.

Felce—Fenemore.—On April 24th, at Widcombe Church, Bath, Stamford Grant Felce, M.A., M.D., B.C. Cantab., to Edith, daughter of the late John Fenemore, of Alcester.

Lewis—Symes-Thompson.—On April 22nd, at St. George's, Hanover-square, Ernest B. Lewis, M.D. Brux., to Lilian, elder daughter of Dr. E. Symes-Thompson.

DEATHS.

Christy.—On the 27th inst., at 21, Princes-chambers, Hanover-square, W., William Beresford Chambers Christy, M.D., late R.N., aged 77 years. Colonial papers please copy.

Finley.—On April 27th, at West Malvern, John Edward McKelvie, the son of Harry Finley, M.D. Lond., aged 13 weeks.

Gerard.—On April 8th, at Perth, of acute phthisis, John Gerard, M.A., M.D. Aberd., M.R.C.P. Lond.

Kirby.—On the 4th March, at his residence, Cerne Abbas, Bournemouth, Edmund A. Kirby, M.D., in his 78th year, dearly loved and deeply mourned.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE "Y" FUND.

Surgeon-General H. S. Muir begs to acknowledge, with thanks, donations towards the "Y" Fund from Lord Rothschild, Sir William H. Broadbent, Bart., K.C.V.O., Sir Thomas Smith, Bart., K.C.V.O., Surgeon-General and Mrs. J. B. Hamilton, Colonel and Mrs. Clibborn, Mrs. Percy D. Cox, Mrs. Munkittrick, Mrs. Charters Symonds, "A Lady" (through Lieutenant-Colonel Drake-Brockman), Mr. Howard Marsh, Sir James R. D. McGrigor, Bart., Mr. E. A. Bliss, Dr. J. E. Squire, Surgeon-Lieutenant J. J. Crean (retired), Lieutenant-Colonel J. H. Reynolds, V.C., A.M.S. (retired), Lieutenant-Colonel W. Babtie, C.M.G., V.C., R.A.M.C., Lieutenant-Colonel J. Anderson, R.A.M.C., Lieutenant-Colonel Emerson, R.A.M.C., and Major W. B. Leishman. It may be explained that this is in response to an appeal made privately to members of the profession for benevolent aid in a distressing case which has been described in a letter sent to a limited number of medical men (who would help the cause by kindly "handing on" to *confrères*). Should any reader of The Lancet desire further particulars with a view to expressing *practical sympathy*, a copy of the letter will be forwarded on application to Surgeon-General Muir, 28, Kensington-gardens-terrace, Hyde Park, London, W.

THE PREHISTORIC REMAINS RECENTLY ACQUIRED BY THE BRITISH MUSEUM.

To the Editors of The Lancet.

Sirs,—In an interesting letter under the above heading in The Lancet of April 26th, p. 1223, Mr. N. Stevenson gives several points worthy of notice; one especially may be enlarged upon. He says: "The dried body is shown just as it was found lying on its left side, with its thighs doubled up under it, in an exact model *of the grave, with all its neolithic flint instruments, &c., in situ.*" There can be no doubt that originally the body was placed *in the sitting posture as is so often found in prehistoric* burial-places, but had lost that position from gravitation. Many bodies were even tied into that doubled-up posture and buried sitting. In other words, in the same position as the human body is in the uterus or womb until within a short time before birth. May we not, then, infer that prehistoric man placed his deceased brother in the tomb or second womb in that same position ready for the second birth or resurrection and credit them with a religious belief, further substantiated by the implements, &c., found entombed with them?

I am, Sirs, yours faithfully,

April 29th, 1902. R. Henslowe Wellington.

A REVOLVING SHELTER FOR PHTHISICAL AND OTHER CASES.

Sanitation writes:—"Could you obtain for me through the medium of the correspondence column of The Lancet information as to the best class of 'revolving shelter' for phthisical and other cases, with a reference to any existing shelters of this class in English sanatoriums?" Our correspondent is in charge of a highly important public institution and we shall be obliged to anyone who can give him the information that he seeks.

MAXIMA DEBETUR MORTUIS REVERENTIA.

We have all heard of the American ladies whose sense of modesty was such that they clothed the legs of their tables and chairs in nether garments. The following occurrence at one of the great London hospitals is illustrative of feeling every whit as nice. A cold storage chamber was being constructed in connexion with the post-mortem room and the secretary of the hospital, on going to see how the work was getting on, found that the chamber was being fitted with double doors—and those of small size—instead of one large door. He made inquiries as to the reason for this deviation from the original plan, when the chief carpenter, who was superintending the work, replied: "Oh, sir, we are putting in double doors and a wooden partition in order to keep the sexes apart"!

FOREIGN MEDICAL LITERATURE.

To the Editors of The Lancet.

Sirs,—Could any of your readers give me the names of the leading German and Austrian medical weeklies and monthlies—those corresponding to The Lancet and the *American Journal of the Medical Sciences*? Who are the leading medical booksellers of Berlin and Vienna?

I am, Sirs, yours faithfully,

April 28th, 1902. Northern Reader.

ACUTE LUMBAGO.

To the Editors of The Lancet.

Sirs,—I beg to bring before your readers a treatment which I have adopted in this common disease and which I have no hesitation in saying will give relief quicker than the usual belladonna liniments or plasters. The patient is put in bed and is surrounded with blankets. The bowels are cleared out by giving a saline purge, followed by a mixture of salicylate of soda, bicarbonate of potassium, and wine of colchicum. Then a compress is made by taking a piece of mackintosh

18 by 10 inches, to this being fixed two layers of flannel 16 by 8 inches; these are stitched to a broad flannel bandage, or, what is better, the compress is fastened to the inner surface of a pair of pants, the pad having been soaked in a strong solution of salicylate of soda (one drachm to one ounce). This is kept applied to the lumbar region. Next an indiarubber bottle filled with boiling water is placed against the loins. From personal experience I can recommend this treatment to any of my medical brethren should they unfortunately suffer from this very painful complaint.—I am, Sirs, yours faithfully,

April 29th, 1902. M.D.

P.S.—The diet should consist of milk and milk puddings, with plenty of lithia water to drink.

THE ETIOLOGY OF BALDNESS.

MANY are the causes of baldness. In THE LANCET of April 5th, p. 983, we drew attention to some recent suggestions issued by the New York Board of Health as to greater precautions against septic infection in the appliances used by hairdressers. Dr. A. R. Reynolds, Commissioner of Health of Chicago, has expressed in the *Chicago Tribune* his doubt of the importance of microbic infection in causing baldness and he lays stress on the harmful effect on the hair produced by the pressure of the ordinary hat. There is much to be said in favour of this theory, for the pressure of the hat on the scalp is often shown by the redness produced. Yet few dermatologists will admit that such pressure is the sole or even the chief cause. Baldness frequently extends backwards beyond the line of pressure of the hat, and nowhere does the margin exactly coincide with the edge of the hat. Before hats were worn baldness existed. To quote only one instance, Julius Cæsar is said to have been very bald, and he certainly did not wear a hat. Nevertheless anything that interferes with the nutrition of the scalp must favour the action of harmful micro-organisms, and therefore tightly-fitting hard hats will certainly hasten the loss of the hair of the head.

FILTHY ADVERTISEMENTS.

To the Editors of THE LANCET.

SIRS,—A long time back I sent you some papers and pamphlets I received from some filthy beast advertising in the *Weekly Times and Echo*. Someone, I do not know whom, has sent me another copy of the same paper in which I see the same advertisement still appearing. I send it on to you. I know you have done a vast amount of good in stopping many papers from advertising such abominations, and it is to be hoped that before long it will be punishable for them to do so.

I am, Sirs, yours faithfully,

Denman Island, B.C., Canada, April 9th, 1902. G. D. B.

TO THE MARRIED,

and THOSE INTENDING to MARRY of Both Sexes.

Read carefully my new book, which treats Every Branch of this Delicate Question of Large Families, with a check as commended by an eminent London Physician. Send Postal at once Order for 1s. 6d., with address plainly written, to Mr. WILTON DOUSE, Science Demonstrator, 7, The Chase, Nottingham.

A New Edition, in sealed packet, for 1s. 6d.

PROPOSED MEMORIAL TO THE LATE SURGEON-GENERAL W. NASH, A.M.S.

MEDICINE IN ANTIQUITY.

IN a recent volume of the Berlin classical journal *Hermes*, a learned German, Herr Wellmann, has been giving some notes upon the History of Medicine in Antiquity, and with Teutonic fervour has suggested as fully ascertained facts the following statements with regard to certain medical authors which we give, shortly summarising Herr Wellmann's views, for what they are worth. Speaking of Athenæus, who it will be remembered gives an account of being present at a Roman banquet with Galen as another of the guests, he says: "The medical citations in his book I. to III. are derived from some critic of Hippocrates, which critic flourished before Varro but subsequently to Hikesius, as his views upon wine and water indicate. This must have been Heraclides of Tarentum, whose 'Symposium' was a compilation of rules for eating and drinking."

Chrysippus, the pupil of Eudoxus, whose books, now lost, are frequently quoted by Galen, speaks of curing the spitting of blood by binding the limbs to prevent inflammation. This shows that he knew Praxagoras's theory that the veins contained the blood, the arteries only air. Chrysippus's information as to the observation of fever by means of the pulse is also from Praxagoras. Herr Wellmann says that Chrysippus flourished therefore about 300 B.C., but that is the date which British scholars previously assigned to him. His famous pupil, Erasistratus, was physician at the Court of the Ptolemies. He was supposed to have been previously at the Syrian Court of Seleucus Nicator and there cured the young Antiochus, but Herr Wellmann shows that it was his father Cleombrotus who achieved this. Another German writer, Dr. von Oefele, has now for many years devoted much time to the study of the medical knowledge of the ancient Babylonians, Assyrians, and Egyptians. The vastly improved interpretations of the languages and writings of these peoples have now made such an undertaking more profitable than it could have been a quarter of a century ago. The result of Dr. von Oefele's investigations in the Asiatic kingdoms is incorporated in the first volume of Neuburger's and Pagel's "Handbuch der Geschichte der Medizin," where many cuneiform prescriptions and medical matters are dealt with. He has also fully described one branch of Egyptian medicine in the fourth volume of the "Archives de Parasitologie." It is well known what an important place among diseases those due to parasites occupy in Egypt and they appear to have been equally prevalent in ancient times.

INCONTINENCE OF URINE.

To the Editors of THE LANCET.

SIRS,—I recently saw in THE LANCET a prescription recommended for incontinence of urine consisting of benzoate of soda, &c. Being in charge of the "incontinent" hut here I tried it on all my "incontinent" patients for some time without the slightest effect. A discussion took place among medical officers here concerning the strength of liquor opii sedativus, some quoting Martindale and Westcott, ninth edition, in favour of its being the same strength as tinctura opii—e.g.: "Extract of opium ...... is of same strength as tincture of opium ...... Resembles Battley's liq. opii sedativus." On the other hand, "Squire" says that it is "say 50 per cent." stronger than tinctura opii. Which is correct? I am, Sirs, yours faithfully,

CIVIL SURGEON.

Connaught Hospital, Aldershot, April 29th, 1902.

*** Liquor opii sedativus is Battley's solution. The liquid extract of opium and the tincture of opium are, according to the latest edition of the British Pharmacopœia, of the same strength as regards morphine—i.e., they should contain 0·75 of a gramme of morphine in 100 cubic centimetres. Probably when "Martindale" says "resembles," it is implied that Battley's solution is made from extract of opium instead of opium and with water instead of spirit in the same way as the liquid extract of opium is made.

WANTED—A HOME.

To the Editors of THE LANCET.

SIRS,—Could you or any of your readers inform me whether there is any hospital or sanatorium (by preference in the Midlands) where a working-man could be immediately taken in for open-air treatment for phthisis? His employers would be willing to pay a guinea a week (if necessary perhaps a little more) for maintenance.

I am, Sirs, yours faithfully,

O. F. FROHWEIN.

48, Lichfield-street, Burton-on-Trent, April 29th, 1902.

THE ROENTGEN RAYS IN CANCER.

To the Editors of THE LANCET.

SIRS,—I should be glad if you or any of your readers could give me any information as regards institutions where the effect of Roentgen rays has been tried in cases of cancer unfitted for operation and the addresses and terms of such institutions.

I am, Sirs, yours faithfully,

April 28th, 1902. M.R.C.S.

◆

Justice.—The members of the club in question are not persons who ought to obtain their medical attendance at such a price as 1*d*. per week or less. Grocers, publicans, butchers, naval pensioners, &c., should be able to pay their medical man properly and their presence on the lists of this amalgamation forms a good argument for the institution of a wage-limit. In answer to the particular questions: 1. It does not seem to us to matter whether the committee which has written so ignorantly and contemptuously concerning the medical profession considers itself badly treated or not. 2. The medical men would be justified in resigning their posts and in endeavouring to prevent other medical men from accepting them. We shall be happy to second their endeavours. 3. The salaries quoted are the usual ones. They are calculated at the lowest rate and account for the "ambition of young medical practitioners" to cut themselves free from such lay organisations.

M.R.C.S., L.R.C.P.—We do not think that the druggist's proceeding can be construed as an infringement of the Medical Act.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—*Torquay Times, Midland Express, Aberdeen Free Press, Weekly Free Press (Aberdeen), Bristol Mercury, Madras Journal, Reading Mercury, Mining Journal, Hertfordshire*

Mercury, Local Government Chronicle, Sanitary Record, Nuneaton Chronicle, Derbyshire Courier, Surrey Advertiser, Local Government Journal, Carpenter and Builder, Rotherham Express, Liverpool Daily Post, Sunday Times, Journal of Tropical Medicine, Westminster Gazette, Knowledge, Broad Arrow, &c.

HURSDAY (8th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

RIDAY (9th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.). West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square, (9.30 A.M.), City Orthopædic (2.30 P.M.).

ATURDAY (10th).—Royal Free (9 A.M. and 2 P.M.), London (2 P.M.) Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.), Throat, Golden-square (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

TUESDAY (6th).—PATHOLOGICAL SOCIETY OF LONDON (Middlesex Hospital, W.).—8 P.M. Laboratory Meeting. Dr. Klein: A New Pathogenic Bacterium.—Mr. T. J. Bokenham: The Action of High Frequency Currents on Bacteria.—Mr. A. G. R. Foulerton and Dr. A. M. Kellas: The Action of High Frequency Currents on Bacteria.—Dr. A. P. Voelcker: A Case of Aneurysm of the Heart.—Dr. C. Thomson: A Case in which a Hat-pin remained embedded in the Heart during Life.—Mr L. Milburn: An Epidemic simulating Tuberculosis in Guinea pigs.—Mr. N. B. Harman: A Method of Demonstrating the Track of Bullet Wounds of the Brain.—Dr. Seligmann: The Inhibitory Action on Bacteria of the Fluid from Charcot Joints.—Mr. H. J. Curtis: Specimens showing the Results of Experimental Yeast Infection.

WEDNESDAY (7th).—OBSTETRICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8 P.M. Specimens will be shown by Mr. A. Doran, Dr. McCann, Dr. R. Vincent, and others. Paper:—Dr. J. S. Fairbairn: Five Specimens of Fibroid Tumour of the Ovary, with Observations on their Pathological Anatomy.

THURSDAY (8th).—BRITISH GYNÆCOLOGICAL SOCIETY (20, Hanover-square, W.).—8 P.M. Specimens will be shown by Prof. A. Smith, Dr. H. Macnaughton-Jones and others. Paper:—Dr. B. Fenwick: Fifty Laparotomies.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne-street, Edgware-road, W.).—8.30 P.M. Discussion on the Early Diagnosis of Specific Fevers (opened by Dr. Sidney P. Phillips).

FRIDAY (9th).—ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND (Charing Cross Hospital Medical School).—4.30 P.M. Papers by Dr. J. M. H. MacLeod and Dr. M. Tims. Preparations by Dr. A. Keith, Dr. C. Addison, Mr. B. J. A. Moynihan, and Mr. F. W. Jones.

CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8.30 P.M. Papers:—Mr. W. G. Spencer: Congenital Diffuse Lymphangioma terminating in Lympho-sarcoma in a Child aged four years.—Mr. G. Turner: Sarcoma of the Ankle Joint.—Mr. C. B. Lockwood: Sarcoma of the Synovial Membrane.—Dr. W. Ewart and Dr. I. Owen: A Case illustrating the Clinical Features of "Horizontal" Dilatation of the Left Auricle.—Dr. I. Owen: "Horizontal" Dilatation of the Left Auricle.—Dr. W. Ewart: A Note on Palpable Systolic Intercostal Pulsation in a Case of Mitral Stenosis, with Dilatation and Thrombosis of the Left Auricle.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (5th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. J. F. Payne: Clinique. (Skin.)

TUESDAY (6th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. C. T. Williams: Clinique. (Medical.)

WEDNESDAY (7th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. J. Hutchinson, jun.: Clinique. (Surgical.)

THURSDAY (8th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. Hutchinson: Clinique. (Surgical.)

CHARING-CROSS HOSPITAL.—4 P.M. Dr. Green: Cases in the Wards. (Post-Graduate Course.)

FRIDAY (9th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. M. Gunn: Clinique. (Eye.)

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

Communications, Letters, &c., have been received from—

A.—Messrs. Allen and Hanburys, Lond.; Apollinaris Co., Lond.; Messrs. Ayrton and Saunders, Liverpool; Association for the Oral Instruction of the Deaf and Dumb, Lond.; Dr. A. G. Auld, Lond.; Mr. R. J Albery, Lond.

B.—Mr. Thomas Bryant, Lond.; Dr. A. Bronner, Bradford; Mr. A. A. Bradburne, Aldershot; Birmingham and Midland Ear and Throat Hospital, Secretary of; Messrs. J. Bale, Sons, and Danielsson, Lond.; Brin's Oxygen Co., Lond.

C.—Dr. R. Craven, Blackburn; Dr. A. Carbonetti, Badia Calavena, Italy; Mrs. Cox, Theale; Dr. W. H. Corfield, Lond.; Messrs. Carfax and Co., Lond.; Messrs. Cassell and Co., Lond.; Dr. Clado, Paris; Cafolin Co., Lond.; Commissioner of Police of the Metropolis, Lond.; City of London, Medical Officer of Health of; Church Sanitary Association, Hon. Secretary of; Mr. C. Couturieux, Paris.

D.—Mr. J. Duncan-Howe, Preston; Messrs. S. Deacon and Co., Lond.; Mr. E. Darke, Lond.; Durham County Asylum, Winterton, Steward of.

E.—Messrs. Evans, Lescher, and Co., Lond.; Evelina Hospital for Sick Children, Lond., Secretary of; E. C. S.

F.—Mr. W. C. Finch, Salisbury; Mr. T. Farrow, Lond.

G.—Dr. J. Galloway, Lond.; Dr. A. S. Gubb, Lond.; Messrs. A. E. Gibson and Co., Lond.; Great Western Cereal Co., Lond.; Messrs. Graham and Shepherd, Sunderland; Glasgow Southern Medical Society, Editorial Secretary of; Government Laboratory, Lond., Principal Chemist of,

H.—Mr. J. Hern, Darlington; Mr. W. R. Horncastle, Lond.; Hardon Star, Lewis and Sinclair Co., Lond.; Harveian Society, Lond., Hon. Secretary of; Messrs. Haasenstein and Vogler, Geneva; Mr. B. W. Housman, Stockport; Staff-Surgeon W. E. Home, R.N.

I.—International Plasmon, Lond.

J.—St. John Ambulance Brigade, Secretary of.

K.—Dr. C. F. Knight, Edinburgh; Messrs. R. A. Knight and Co., Lond.

L.—Mr. Harry Lupton, Reading; Liverpool Stanley Hospital, Secretary of; Mr. W. W. Linington, Folkestone; London Nut Food Co., Secretary of; Llandrindod Wells Urban District Council, Clerk of; L. C.; Libreria Detken and Rochel, Naples.

M.—Dr. E. P. McLoughlin, Lond.; Messrs. C. Mitchell and Co., Lond.; Medical Defence Union; Lond., General Secretary of, Manchester Medical Agency, Secretary of; Metropolitan Police Office, Lond., Chief Clerk of; Mr. W. L. Moore, Newport, Mon.; Miss M. Moran, Lond.;

N.—Dr. David Newman, Glasgow; Dr A. Newsholme, Brighton; Dr. H. O. Nicholson, Edinburgh; Northern Reader; Captain W. J. Niblock, I.M.S., Madras; Northcote Hydro, Woodhall Spa; Mr. H. Needes, Lond.; Mr. J. C. Needes, Lond.

P.—Mr. Y. J. Pentland, Edinburgh; Paisley, Medical Officer of Health of; Dr. R. Paramore Lond.

R.—Ragged School Union, Secretary of; Mr. E. J. Reid, Lond.; Messrs. Rowntree and Co., York; Royal Albert Hospital, Devonport, Secretary of; Rebman, Ltd., Lond.; Royal National Pension Fund for Nurses, Lond., Secretary of.

S.—Mr. N. Stevenson, Lond.; Messrs. Squire and Son, Lond.; Mr. C. S. Stevens, Lond.; Mr. Noble Smith, Lond.; Mr. F. W. Sears, Lond.; St. John's Hospital for Diseases of the Skin, Lond.; Major B. M. Skinner, R.A.M.C., Lond.; Professor J. Lindsay Steven, Glasgow; Dr. W. H. B. Stoddart, Lond.; Messrs. G. Street and Co., Lond.; Messrs. W. B. Saunders and Co., Lond.; Scholastic, Clerical, &c., Association, Lond.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not onl affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies onl should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manage Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed

THE LANCET can be obtained at all Messrs. W H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Adver tisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

A Baillie Lecture

ON

THE SEED AND THE SOIL.

Delivered at St. George's Hospital on Feb. 3rd, 1902,

BY W. HOWSHIP DICKINSON, M.D. CANTAB., F.R.C.P. LOND.,

HONORARY FELLOW OF GONVILLE AND CAIUS COLLEGE, CAMBRIDGE; CONSULTING PHYSICIAN TO ST. GEORGE'S HOSPITAL AND TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

"Behold, the sower went forth to sow; and as he sowed, some seeds fell by the way side, and the birds came and devoured them: and others fell upon the rocky places, where they had not much earth: and straightway they sprang up, because they had no deepness of earth: and when the sun was risen, they were scorched: and because they had no root, they withered away. And others fell upon the thorns; and the thorns grew up, and choked them: and others fell upon the good ground, and yielded fruit, some a hundredfold, some sixty, some thirty."—MATTHEW xiii. 3.

GENTLEMEN,—The pathology of the present day is above all things bacteriological. It inclines to attribute all diseases with which bacteria have been associated simply and singly to a bacterial origin, confidently assumes that where microbes have not yet been found they will be, and sanguinely trusts that when found they will submit to control with a tractability in the future which our experience of the past gives us no great warrant to expect. I read the other day in THE LANCET of a bacillus of fatigue and should hear without astonishment of bacilli of political or theological bias impelling their bearers to toryism or radicalism, scepticism or credulity.

One of the greatest discoveries of the past century, I may even say of all time if greatness be measured by utility, is connected with the recognition of micro-organisms, their exclusion by cleanliness and destruction by antiseptics. But it must be allowed that antiseptic surgery is more successful than is antiseptic medicine; the two are on very different footings: one has to do chiefly with suppuration, in the first instance at least a question of reachable surface; the other has to do with disease which is out of reach before it comes to our knowledge and has entrenched itself in the deep organs or found a harbour in the blood itself. One is chiefly concerned with the streptococcus and staphylococcus, comparatively simple sources of mischief, the other with bacilli of various kinds and complicated relations with disease.

Encouraged as we must be by the results of antiseptic surgery, we must approach with wary steps the very dissimilar problems which medicine presents. To these my text chiefly applies. I would venture to beg my hearers not to be so eager to secure what is new that they lose what has been acquired in the past. In grasping the new pathology of microbes and bacilli let us not quite ignore the ascertained facts of old time with regard to heredity, tissue and diathesis. It is for the purpose of recalling some of the old truths, none the less true because they are out of fashion, that I address you to-day.

Bacilli may be the roots, or rather the seeds, of much, if not of all, evil. It seems to us that we should get on better without them. But let us not be too sure of that; some sorts have uses that we know of; others may have uses that we do not know of. They take their part in the scheme of creation, though to us it may be a mischievous one.

"From Nature's chain whatever link you strike,
Tenth, or ten thousandth, breaks the chain alike."

As to the bacilli of disease, we from the human point of view cannot but regard them with disapproval. Our soul's sincere desire must be to get rid of them. But, unfortunately, like other enemies, they are not very amenable to frontal attack. They are more readily influenced by indirect than direct methods, by means which without bearing immediately on the bacillus render its abode unattractive or untenable.

We may learn much from the vegetable kingdom. The distribution of plants, within the range of the seed, is regulated by the local conditions which the seed meets with—soil, moisture, temperature, light, and what not. Of course, there is no growth without the seed. *Omne vivum ex ovo* holds good now as in the time of Harvey. But the seed may be indiscriminately and widely spread; within certain wide boundaries it may often be said to be ubiquitous, so that the whole question of distribution turns not upon the seed but the soil, not upon the germ but its reception. Why do oaks and beeches grow in the fat levels of the New Forest, the ash and the thorn where the land is hilly and poor, and sycamores about the wind-swept homesteads of Cornwall? Not because the seed was, in the first instance, placed there more than elsewhere, but being placed there, as elsewhere, it found conditions to suit it. This is the whole story of the whereabouts of plants; the supreme law of the vegetable kingdom. The seed will fructify where it is satisfied with its entertainment and perish where it is not. For this reason, and not because the seed is conveyed there more than elsewhere, stonecrop, moss, and lichen gather on their appropriate roofs and rocks and the ivy on mouldering walls. Thus ferns multiply in their variety in one district and not in another. Ferns flourish with warmth and moisture and assure us by their presence of these qualities in the atmosphere. Maidenhair has its chosen localities in shady caves and crannies where the necessary conditions are combined, and may be so far from any other growths of the same sort that we can but wonder whence the seed was derived. Passing from natural beauty to what is repulsive we learn a similar lesson from the degraded nettle with its associations of squalor and filth. The seed may be everywhere in a country district but the weed will be found especially where human excrement has been deposited.

Examples of the paramount influence of soil or nidus in the determination of vegetable and animal life are never absent from our eyes. Take the domestic cheese. Why does one cheese breed green mould, another mites, and a third maggots? It may be that the three are kept in the same larder, exposed to the same external influences, and sown with the same seeds of animal and vegetable decay. Yet in the Stilton will gather green mould, in a fat cheese maggots, and in a lean one mites. The difference is in the cheeses themselves, not in what they have been sown with. The germs are common to all; those only will germinate which like their situation. So it is when the soil is the human body. Germs, be they vegetable or animal, are continually on the wing or in the swim; they swarm around us on every side; and if we knew how many and of what sorts are continually besprinkling us with the seeds of disease we should live in continued dread of being assassinated by these minute enemies. It is probable that no one who has lived in London has failed to give lodgement to the organism of typhoid fever, though he may have escaped its effects, and so with many other diseases. So it must be presumed to be with most of the infectious disorders which are common in ordinary life. Why is it, then, that we are not all infected with everything?

Relapsing fever may supply an illustration. This disease is occasioned by a special bacterium, the spirillum, which finds admission into the blood, presumably always by way of contagion. Yet it is intimately associated with starvation, insomuch that its accepted synonym is famine fever. The disorder is not directly caused by starvation but by the spirillum which is descended from its own kind. The want of food does not directly engender the microbe but fits the body for its entertainment. Given the suitable state of body, the appropriate germ will find it out though to our imagination completely out of reach. Our exemption rests not so much on the absence of the bacillus as on the absence of the conditions which it requires. Our forefathers did not fail to notice the connexion between depression and febrile disorders which is exemplified by remittent fever and possibly applies also in some degree to typhus fever. Says Addison, in the *Tatler*: "Physicians observe that the poorest and most dispirited blood is most subject to fevers."

Limiting the dissemination of the morbific germs by isolation is at best an imperfect measure. Our salvation largely depends on our insusceptibility, though, of course, we sometimes have to thank the feebleness or attenuation of the poison which reaches us. The human body can deal with a certain amount of the seeds of disease without becoming diseased. There is such a process as phagocytosis, in virtue of which the white corpuscles play the part of the birds and devour the seeds. There is such a condition as immunity even when the poison is active and concentrated, a state which may be either congenital or acquired, which is very real however imperfectly understood, by reason of
